ABSTRACT

This paper presents computationally efficient and accurate semi-empirical models of light transfer for real-time diffuse reflectance spectroscopy. The models predict the diffuse reflectance of both (i) semi-infinite homogeneous and (ii) two-layer media exposed to normal and collimated light. The two-layer medium consisted of a plane-parallel slab of finite thickness over a semi-infinite layer with identical index of refraction but different absorption and scattering properties. The model accounted for absorption and anisotropic scattering as well as for internal reflection at the medium/air interface. All media were assumed to be non-emitting, strongly forward scattering, with index of refraction between 1.0 and 1.44 and transport single scattering albedo between 0.50 and 0.99. First, simple analytical expressions for the diffuse reflectance of the semi-infinite and two-layer media considered were derived using the two-flux approximation. Then, parameters appearing in the analytical expression previously derived were instead fitted to match results from more accurate Monte Carlo simulations. A single semi-empirical parameter was sufficient to relate the diffuse reflectance to the radiative properties and thickness of the semi-infinite and two-layer media. The present model can be used for a wide range of applications including non-invasive diagnosis of biological tissue.
1 INTRODUCTION

Diffuse reflectance spectroscopy consists of determining the radiative properties of an absorbing and scattering sample from diffuse reflectance measurements. It has been applied to non-invasive health-monitoring of in-vivo biological tissues [1–7], quality control in agricultural applications [8–12], and remote terrestrial sensing [13–16], for example. In many biological applications, the irradiated medium can be modeled as a strongly scattering multi-layer medium whose radiative properties are constant within each layer but differ from layer to layer. For example, the human cervix [17], colon [18], and skin [19] have been modeled as two-layer optical systems. Skin consists of an outer layer called the epidermis and of an underlying layer called the dermis. The epidermis is characterized by strong absorption in the ultraviolet and visible part of the spectrum due to melanin. On the other hand, the blood and connective tissues are responsible for absorption and scattering in the dermis. In addition, the absorption characteristics of blood depend on the concentrations of oxy- and deoxy-hemoglobin [20].

Light transfer through turbid media such as biological tissues is governed by the radiative transfer equation (RTE). The latter expresses an energy balance in a unit solid angle $d\Omega$, about the direction $\hat{s}$ at location $\hat{r}$. The steady state RTE in a homogeneous, absorbing, scattering, but non-emitting medium is expressed as [21,22],

$$\hat{s} \cdot \nabla I_\lambda(\hat{r}, \hat{s}) = -\mu_{a,\lambda}I_\lambda(\hat{r}, \hat{s}) - \frac{\mu_{s,\lambda}}{4\pi} \int_{4\pi} I_\lambda(\hat{r}, \hat{s}_i)\Phi_\lambda(\hat{s}_i, \hat{s})d\Omega_i$$

(1)

where the intensity at location $\hat{r}$ and in direction $\hat{s}$ is denoted by $I_\lambda(\hat{r}, \hat{s})$ and expressed in W/cm$^2$ · sr · nm. The linear spectral absorption and scattering coefficients are denoted by $\mu_{a,\lambda}$ and $\mu_{s,\lambda}$, respectively and are expressed in cm$^{-1}$. The scattering phase function denoted by $\Phi_\lambda(\hat{s}_i, \hat{s})$ represents the probability that radiation propagating into the elementary solid angle $d\Omega_i$ around direction $\hat{s}_i$ will be scattered in direction $\hat{s}$. The first and second terms on the right-hand side of Equation (1) represent the attenuation of the radiation intensity due to absorption and out-scattering, respectively. The last term corresponds to the augmentation of radiation due to in-scattering from all directions $\hat{s}_i$ into direction $\hat{s}$. The contribution of scattering to the overall extinction is represented by the single scattering albedo $\omega_\lambda$ expressed as,

$$\omega_\lambda = \frac{\mu_{s,\lambda}}{\mu_{a,\lambda} + \mu_{s,\lambda}}$$

(2)

The Henyey-Greenstein scattering phase function is an approximate expression that accounts for the anisotropic nature of scattering and is given by [23],

$$\Phi_\lambda(\hat{s}_i, \hat{s}) = \frac{1 - g_\lambda}{(1 + g_\lambda^2 - 2g_\lambda \cos\Theta)^{3/2}}$$

(3)

The Henyey-Greenstein asymmetry factor $g_\lambda$ is the first moment of the scattering phase
function and is defined as [23],

\[ g_\lambda = \frac{1}{4\pi} \int_{4\pi} \Phi_\lambda(\hat{s}_i, \hat{s}) \cos \Theta d\Omega_i \]  (4)

It varies between -1 and 1. If scattering is isotropic, then the phase function is constant and \( g_\lambda \) equals 0. For \( g_\lambda \) close to -1 and 1, scattering is strongly backward or forward, respectively. The Henyey-Greenstein phase function depends only on \( g_\lambda \) and has been used extensively in tissue optics [4, 24, 25], computer animation [26, 27], and astronomy [28, 29], to name a few.

For the sake of clarity, the dependence of the radiative properties on wavelength will be assumed and the subscript “\( \lambda \)” omitted henceforth. Furthermore, all analysis and results will be presented in terms of the transport single scattering albedo \( \omega_{tr} \) defined as,

\[ \omega_{tr} = \frac{\mu_{s, tr}}{\mu_{s, tr} + \mu_a} = \frac{\mu_s(1 - g)}{\mu_s(1 - g) + \mu_a} \]  (5)

Here, \( \mu_{s, tr} = \mu_s(1 - g) \) is the transport scattering coefficient which accounts for both the magnitude and anisotropy of the scattering phenomenon [21]. For example, in case of complete forward scattering, i.e., \( g = 1.00 \), scattering has no effect on the propagation of light through the medium and \( \mu_{s, tr} = 0.0 \) [21].

The objective of this study is to develop simple and accurate expressions for the diffuse reflectance \( a \) of semi-infinite and a two-layer absorbing and scattering media. Such expressions could be combined with an inverse method to retrieve the radiation properties and thickness of these media based on spectral diffuse reflectance measurements.

## 2 BACKGROUND

Explicit analytical solutions of the RTE can be found only for a limited range of geometries and for simplified scattering phase functions [21, 30]. Approximate or numerical solutions can be obtained based on the two-flux approximation or Monte Carlo simulations, for example.

### The Two-Flux Approximation

The one-dimensional RTE can be solved by the well-known two-flux approximation [31, 32] (also called the Kubelka-Munk theory) in which the forward and backward fluxes are defined as,

\[ F^+(z) = 2\pi \int_0^{\pi/2} I(z, \theta) \cos \theta \sin \theta d\theta \quad \text{and} \quad F^-(z) = -2\pi \int_{\pi/2}^{\pi} I(z, \theta) \cos \theta \sin \theta d\theta \]  (6)

where \( z \) is the depth within the medium estimated from the front surface and \( \theta \) is the angle measured from the inward normal (see Figure 1). Then, the RTE simplifies to a set of two coupled linear equations [31, 32],

\[ \frac{1}{S} \frac{dF^+}{dz} = -aF^+ + F^- \]  (7)

\[ \frac{1}{S} \frac{dF^-}{dz} = -F^+ + aF^- \]  (8)

3
with \( a = (S + K)/S \) where \( K \) and \( S \) are the Kubelka-Munk (K-M) absorption and scattering coefficients, respectively. They do not have any physical meaning [33] but are related to the radiative properties \( \mu_a \) and \( \mu_{s, tr} \) and depend on the scattering phase function.

Equations (7) and (8) have been solved for a variety of slab geometries and boundary conditions. Saunderson [34] used the two-flux approximation to predict the diffuse reflectance, denoted by \( \tilde{R}_-(a) \), of a semi-infinite homogeneous medium exposed to collimated and normally incident radiation with index mismatch at the air/medium interface as [34],

\[
\tilde{R}_-(a) = \rho_{01} + (1 - \rho_{01})(1 - \rho_{10}) \frac{\tilde{R}_d(a)}{1 - \rho_{10}\tilde{R}_d(a)}
\]

where \( \tilde{R}_d(a) = a - \sqrt{a^2 - 1} \) is the diffuse reflectance of semi-infinite medium exposed to diffuse irradiation as predicted by the two flux approximation. Note that the first term \( \rho_{01} \) corresponds to the specular reflection of incident radiation by the surrounding/medium interface while the second term accounts for the back-scattered radiation. The specular reflectivity for normally incident radiation denoted by \( \rho_{01} \) is defined as [21],

\[
\rho_{01} = \left( \frac{n_1 - n_0}{n_1 + n_0} \right)^2
\]

The hemispherical-hemispherical reflectivity \( \rho_{10} \) is the fraction of radiation from within the medium reflected back into the medium due to index mismatch [35] and assumed to be diffusely incident upon the medium/air interface. It is given by [34–36],

\[
\rho_{10} = \int_{0}^{\pi/2} \rho''(\theta_i) \sin 2\theta_i d\theta_i
\]

where \( \rho''(\theta_i) \) is the directional specular reflectivity of the interface for angle of incidence \( \theta_i \) expressed as [21],

\[
\rho''(\theta_i) = \begin{cases} 
\frac{1}{2} \left[ \frac{\sin^2(\theta_i - \theta_t) + \tan^2(\theta_i - \theta_t)}{\sin^2(\theta_i + \theta_t)} + \frac{\tan^2(\theta_i + \theta_t)}{\tan^2(\theta_i + \theta_t)} \right] & \text{for } \theta_i \leq \theta_c \\
\frac{1}{2} \left[ \frac{\sin^2(\theta_i + \theta_t) + \tan^2(\theta_i + \theta_t)}{\sin^2(\theta_i - \theta_t)} + \frac{\tan^2(\theta_i - \theta_t)}{\tan^2(\theta_i - \theta_t)} \right] & \text{for } \theta_i > \theta_c
\end{cases}
\]

where \( \theta_t \) is the angle of transmittance given by Snell’s law (i.e., \( n_0 \sin \theta_t = n_1 \sin \theta_i \)) and \( \theta_c \) is the critical angle defined as \( \theta_c = \sin^{-1}(n_0/n_1) \) [21].

Moreover, the diffuse reflectance of a two-layer system composed of a plane-parallel slab (layer 1) of thickness \( L_1 \) over a semi-infinite layer (layer 2) exposed to collimated and normally incident irradiation has been derived as [34,35],

\[
\tilde{R}_=(a_1, a_2, Y_1) = \rho_{01} + \frac{(1 - \rho_{01})(1 - \rho_{10})[b_1\tilde{R}_d(a_2) + (1 - a_1\tilde{R}_d(a_2)) \tanh(Y_1)]}{b_1(1 - \rho_{10}\tilde{R}_d(a_2)) + [a_1(\rho_{10}\tilde{R}_d(a_2) + 1) - \rho_{10}^2 - \tilde{R}_d(a_2)] \tanh(Y_1)}
\]

where \( a_j = (S_j + K_j)/S_j \), \( b_j = \sqrt{a_j^2 - 1} \) where subscript “j” refers to medium 1 or 2, and the K-M optical thickness is given by \( Y_1 = b_1S_1L_1 \).
If the medium is isotropically scattering then $K = 2\mu_a$ and $S = \mu_{s, tr}$ [21,37]. However, when scattering is anisotropic, $K$ and $S$ depend on $\omega_{tr}$. To find this relationship, the following approximate phase function can be used to reduce the RTE into a form that can be solved analytically [21,22,30,38],

$$\Phi_{\lambda}(\hat{s}_i, \hat{s}) = [4g\delta(1 - \cos \Theta) + (1 - g)]$$

(14)

It has the same zeroth and first moments as the Henyey-Greenstein phase function [Equation (3)] which are equal to 1 and $g$, respectively. Van Gemert and Star [22] showed that the expression of the diffuse reflectance and transmittance found by solving the 1D RTE assuming Equation (14) has the same algebraic form as the solution developed from the two-flux approximation. Then, they developed the following relationship between the $K$-$M$ absorption and scattering coefficients $K$ and $S$ on the one hand and $\mu_a$ and $\mu_{s, tr}$ on the other,

$$\mu_a = \eta K \quad \text{and} \quad \mu_{s, tr} = \chi S$$

(15)

where, $\eta = (\phi - 1)(1 - \omega_{tr})/\zeta(\phi + 1)$ and $\chi = -\omega_{tr}(\phi - \phi^{-1})/(2\zeta)$

(16)

The parameter $\phi$ is given by [22],

$$\phi = \frac{\zeta + \ln(1 - \zeta)}{\zeta - \ln(1 + \zeta)}$$

(17)

where $\zeta$ is the root of the characteristic equation [30],

$$\omega_{tr} = \frac{2\zeta}{\ln[(1 + \zeta)/(1 - \zeta)]}$$

(18)

To simplify the estimation of the diffuse reflectance, we solved Equation (18) numerically and fitted a third order polynomial to yield,

$$\zeta^2 = \frac{47}{52} - \frac{31}{49}\omega_{tr} - \frac{49}{54}\omega_{tr}^2 - \frac{17}{27}\omega_{tr}^3$$

(19)

The relative difference between Equation (19) and the exact solution of Equation (18) was found to be less than 1% for $0.40 < \omega_{tr} < 1.00$. Finally, the K-M optical thickness is given by,

$$Y_1 = \zeta(\mu_a + \mu_{s, tr})L_1 = \zeta\tau_{tr,1}$$

(20)

where, $\tau_{tr,1} = (\mu_a + \mu_{s, tr})L_1$ is the transport optical thickness of a slab of thickness $L_1$ [21].

Monte Carlo Methods

Alternatively, Monte Carlo methods are commonly used to numerically solve the RTE [39–43]. To do so, a stochastic model is constructed such that the expected value of a certain random variable is equivalent to the value of physical quantity that is determined by the exact differential equation [44]. The expected value is estimated by sampling the random variable multiple times. In effect, by repeating the simulation, the variance of the estimate diminishes. Thus, the solution may be found with arbitrary accuracy by increasing the number of simulations, albeit at the cost of time [45].
Therefore, Monte Carlo simulations are difficult to use in inverse methods associated with diffuse reflectance spectroscopy [21]. Indeed, the forward problem of evaluating the diffuse reflectance must be solved numerous times to iteratively determine the medium's radiative properties. Instead, Gardner et al. [41] developed a semi-empirical model for one-dimensional light transfer through a semi-infinite medium exposed to collimated incident radiation based on Monte Carlo simulations. An analytical model of the fluence profile in the medium was developed using the diffusion approximation. The constants of integration, instead of being determined analytically, were found by fitting them to results from Monte Carlo simulations. The predictions of local fluence by the semi-empirical model compared well with results from Monte Carlo simulations and could be rapidly estimated.

The objective of this study is to develop a semi-empirical model for the diffuse reflectance of a non-emitting, absorbing and strongly forward scattering medium consisting of two layers exposed to collimated incident radiation. An approach similar to that used by Gardner et al. [41] but based on the two-flux approximation is developed in this study.

3 METHODS

Model Geometry and Radiative Properties

Figure 1 shows the one-dimensional geometries investigated in this study. First, a homogeneo-

neous semi-infinite slab characterized by \( \mu_a, \mu_s, g, \) and \( n_1 \) was considered. A wide range of property values was explored namely \( 0.3 \leq \omega_{tr} \leq 0.99, 0.70 \leq g \leq 0.90, \) and \( n_1 = 1.00, 1.33, 1.44, 1.77, \) and 2.00.

Moreover, a two-layer medium was considered. It consisted of a plane-parallel slab (Layer 1) characterized by \( \mu_{a,1}, \mu_{s,1}, g_1, n_1 \) and thickness \( L_1 \) supported by a semi-infinite sub-
layer (Layer 2) characterized by \( \mu_{a,2} \) and \( \mu_{s,2}, g_2 \). The polar angle \( \theta \) is taken relative to the inward surface normal. The physical distance from the surface is denoted by \( z \) and measured in centimeters. The thickness of Layer 1, denoted by \( L_1 \), was considered between
0 and infinity. The incident light source was modeled as a collimated, monochromatic, and normally incident beam of infinite radius and intensity $I_0 = q_0 \delta(\theta)$. The quantity $q_0$ denotes the radiative flux of the collimated beam and $\delta(\theta)$ is the Dirac delta function. The air/slab interface and the interface between the slab and the semi-infinite sub-layer are assumed to be optically smooth. Under these conditions, radiative transfer can be considered as one-dimensional [21, 46]. Light scattering was assumed to dominate over absorption in both layers and to be strongly forward. The transport single scattering albedo of the slab $\omega_{tr,1}$ and of the sub-layer $\omega_{tr,2}$ varied between 0.50 and 0.99. The Henyey-Greenstein asymmetry factors of the two layers $g_1$ and $g_2$ varied between 0.70 and 0.90. These ranges correspond, but are not limited to, biological tissues such as the skin, muscle, and brain [4]. Finally, the index of refraction was assumed to be identical within the two layers but different from that of the surroundings. The values of refractive index investigated were $n_1 = n_2 = 1.00, 1.33,$ and $1.44$, corresponding to vacuum, water in the visible [47], and biological tissues in the visible and near-infrared part of the electromagnetic spectrum [4, 24]. The surrounding was assumed to be air or vacuum so that $n_0 = 1.00$.

The one-dimensional RTE given in Equation (1) was solved numerically for both geometries after specifying the boundary conditions and selecting the method of solution.

**Boundary Conditions**

Due to index mismatch, the collimated intensity incident onto the air/slab interface is reflected and refracted according to Fresnel’s equations and Snell’s law, respectively. The flux transmitted through the air/slab interface is $(1 - \rho_{01})q_0$ while the reflected flux is $\rho_{01}q_0$. In addition, light from within the slab and incident onto the slab/air interface at an oblique angle $\theta_i$ is specularly reflected with intensity $\rho''(\theta_i)I(0, \pi - \theta_i)$. On the other hand, light back-scattered from within the medium that is incident on the slab/air interface at an angle $\theta_i$ larger than the critical angle undergoes total internal reflection, as illustrated in Figure 1. Therefore, the boundary conditions of the RTE at the slab/air interface ($z = 0$) can be expressed as [21],

$$I(0, \theta) = (1 - \rho_{01})q_0 \delta(\theta) + \rho''(\theta)I(0, \pi - \theta) \quad \text{for} \quad 0 \leq \theta \leq \pi / 2 \quad (21)$$

Furthermore, the intensity vanishes as $z$ tends to infinity, i.e.,

$$I(z \to \infty, \theta) = 0 \quad \text{for} \quad -\pi \leq \theta \leq \pi \quad (22)$$

Note that no reflection or refraction takes place at the slab/sub-layer interface since they have the same index of refraction. Thus, no boundary conditions need be imposed.

**Method of Solution**

The RTE was solved using the Monte Carlo simulation software developed by Wang and Jacques [48] for simulating light transfer through multilayer non-emitting, absorbing and scattering media. The Henyey-Greenstein scattering phase function, given by Equation (3), was used to account for anisotropic scattering. A complete and detail description of the implementation and theoretical underpinnings of this software is given in Ref. [48].
The variance in the prediction of the diffuse reflectance increases with decreasing single scattering albedo since absorption by the medium dominated over scattering resulting in fewer back-scattered photons. Thus, the number of simulated photon packets per simulation was increased until the variance associated with the estimate of the diffuse reflectance fell below 1% the most stringent case of a homogeneous medium with $\omega_{tr} = 0.50$. Each simulation required 1,000,000 photon packets or less to achieve the convergence criteria.

## Diffuse Reflectance

The total intensity of the light reflected from semi-infinite or two-layer media is the sum of the specularly reflected intensity and the intensity back-scattered by the medium and transmitted through the slab/air interface. In practice, this quantity can be measured in-vivo by a variety of optical instruments such as an integrating sphere coupled to a detector [4]. It is denoted by $I_r(\theta_t)$ and expressed as,

$$I_r(\theta_t) = \rho_{01} q_0 \delta(\pi - \theta_t) + [1 - \rho''(\theta_t)] I(0, \pi - \theta_t) \quad \text{for} \quad 0 \leq \theta_t \leq \pi/2$$  \hspace{1cm} (23)

where $\theta_t$ is given by Snell’s law. The specularly reflected intensity $\rho_{01} q_0 \delta(\pi - \theta_t)$ was ignored in this study. In practice, this is achieved by illuminating the medium with polarized light [49]. The specularly reflected intensity remains polarized and can be filtered by a linear polarizer before reaching the detector [49]. The back-scattered light is depolarized due to multiple scattering in the medium and passes unattenuated through the polarizer filter to reach the detector. Thus, the diffuse reflectance $R$ is defined as the ratio of the back-scattered radiative flux $q_r$ to the incident radiative flux, $q_0$, i.e., $R = q_r/q_0$, where $q_r$ is expressed as,

$$q_r = -2\pi \int_{\pi/2}^{\pi} [1 - \rho''(\theta_t)] I(0, \pi - \theta_t) \cos \theta_t \sin \theta_t d\theta_t$$ \hspace{1cm} (24)

The goal of the study is to develop an expression to rapidly predict the diffuse reflectance of a two-layer medium as a function of its radiative and geometrical properties, namely $n_1 = n_2$, $L_1$, $\mu_{a,1}$, $\mu_{s,1}$, $\mu_{a,2}$, $\mu_{s,2}$, $g_1$, and $g_2$. As an intermediate step, an expression for the reflectance of a semi-infinite medium is developed.

## 4 ANALYSIS

### Semi-Empirical Diffuse Reflectance of Semi-Infinite Media

This section aims to determine the relationship between the diffuse reflectance $R_\perp$ from a semi-infinite layer and its transport single scattering albedo $\omega_{tr}$ with higher accuracy than the original two-flux approximation. Prediction accuracy was calculated relative to results from Monte Carlo simulations. Figure 2 shows the diffuse reflectance $R_\perp$ as a function of $\omega_{tr}$ for $n_1 = 1.00$ for different values of $g$ along with the predictions from the two-flux approximation given by Equations (9) and values of $a$ obtained from Equations (15) to (17) and Equation (19). It is evident that the diffuse reflectance $R_\perp$ increases with $\omega_{tr}$ as scattering dominates
Reduced single scattering albedo, $\omega_{tr}$

Diffuse reflectance, $R_d^-$

$g = 0.70$
$g = 0.75$
$g = 0.80$
$g = 0.85$
$g = 0.90$

Equations (9) and (19)

Figure 2: Diffuse reflectance of a homogeneous semi-infinite medium predicted by Monte Carlo simulations (symbols) and the two-flux approximation [Equations (9) and (19)] (dash line) for $n_1 = 1.00$, $0.3 \leq \omega_{tr} \leq 1.00$, and $0.70 \leq g \leq 0.90$.

over absorption and more light is back-scattered by the medium. Furthermore, the diffuse reflectance is almost completely determined by $\omega_{tr}$ and nearly independent of the Henyey-Greenstein asymmetry factor $g$ in the range of interest. This is known as the similarity relation [38].

Moreover, the reflectance predicted by the two-flux approximation follows a similar trend as that predicted by Monte Carlo simulations (Figure 2). However, the relative difference varies from 100% to 5% as $\omega_{tr}$ increases from 0.3 to 1.0 for all values of $g$ considered. This can be attributed to the fact that Equation (11) used to determine $\rho_{10}$ was derived with the assumption that intensity at the medium/air interface was diffuse [34, 35]. Unfortunately, it is not the case [50]. Thus, unlike Monte Carlo simulations, $\rho_{10}$ used in the two-flux approximation does not accurately account for the optical phenomena at the medium/air interface.

Consequently, Equation (9) predicting the reflectance of a semi-infinite medium was replaced by the following semi-empirical expression,

$$R_-(\omega_{tr}) = \left[1 - \rho_{01}\right]\left[1 - \hat{\rho}_{10}(\omega_{tr})\right] \frac{\hat{R}_d(\omega_{tr})}{1 - \hat{\rho}_{10}(\omega_{tr})\hat{R}_d(\omega_{tr})}$$

(25)

where $\rho_{01}$ is given by Equation (10). To account for the fact that intensity $I(z = 0, -1 \leq \mu \leq 0)$ inside the medium is not diffuse, the reflectivity $\rho_{10}$ and the reflectance $\hat{R}_d$ appearing in Equation (9) were respectively replaced by $\hat{\rho}_{10}$ and $\hat{\hat{R}}_d$ assumed to be polynomial functions.
of $a(\omega_{\text{tr}})$,

\[
\hat{\rho}_{10}(\omega_{\text{tr}}) = \rho_{10} + \sum_{i=0}^{i=N} A_i [a(\omega_{\text{tr}})]^i
\] (26)

\[
\tilde{R}_d(\omega_{\text{tr}}) = \tilde{R}_d(a(\omega_{\text{tr}})) + \sum_{i=0}^{i=N} B_i [a(\omega_{\text{tr}})]^i
\] (27)

where $(A_i)_{0\leq i \leq N}$ and $(B_i)_{0\leq i \leq N}$ are regression coefficients and $N$ is the polynomial order. These parameters were found by minimizing the sum of the squared residuals between the reflectance $R_-$ obtained by Monte Carlo simulations and that predicted by Equations (25) through (27). Numerical results were found for $n_1 = 1.00, 1.33, 1.44, 1.77,$ and $2.00$. The polynomial order $N$ was increased until the residual between the diffuse reflectance determined by Monte Carlo simulations and Equation (25) was small and random. This condition was met with $N = 3$. More precisely, for $0.70 \leq g \leq 0.90$, the residual was less than (i) 10% for $\omega_{\text{tr}} \geq 0.40$, (ii) 5% for $\omega_{\text{tr}} \geq 0.50$, and (iii) 2% for $\omega_{\text{tr}} \geq 0.70$.

Figure 3 shows the diffuse reflectance from a semi-infinite medium as a function of its transport single scattering albedo $\omega_{\text{tr}}$ for different values of $n_1$ and $g$. Predictions by Equa-

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure3.png}
\caption{Diffuse reflectance of a semi-infinite homogeneous medium predicted by Monte Carlo simulations and Equations (25) for $n_1 = 1.00, 1.33, 1.44, 1.77,$ and $2.00, 0.3 \leq \omega_{\text{tr}} \leq 1.0,$ and $0.7 \leq g \leq 0.9.$}
\end{figure}

...tions (25) through (27) are also plotted for the regression coefficients $(A_i)_{0\leq i \leq 3}$ and $(B_i)_{0\leq i \leq 3}$ reported in Table 1. The similarity relationship previously observed for the case of $n_1 = 1.00$ (Figure 2) was also valid for other values of $n_1$. Thus, the diffuse reflectance of a semi-infinite medium $R_-$ is only a function of (i) the index of refraction $n_1$ and (ii) the transport single scattering albedo $\omega_{\text{tr}}$.

**Diffuse Reflectance of Two-Layer Media - Two-Flux Approximation**

Figure 4a shows the diffuse reflectance of the two-layer medium \(\tilde{R}_-(a_1, a_2, Y_1)\) predicted by Equation (13) as a function of the K-M optical thickness \(Y_1\) for 9 pairs of parameters \(a_1\) and \(a_2\) varying between 1 and 6 while \(\rho_{01} = 0.033\) and \(\rho_{10} = 0.56\). These values corresponds to \(\omega_{t,1}\) and \(\omega_{t,2}\) varying between 0.50 and 1.00, \(n_0 = 1.00\) and \(n_1 = n_2 = 1.44\). Figure 4a shows that the diffuse reflectance of the two-layer medium progresses from \(\tilde{R}_-(a_2)\) to \(\tilde{R}_-(a_1)\) as \(Y_1\) increases from \(10^{-3}\) to 6. Indeed, there are two asymptotic cases,

\[
\tilde{R}_-(a_1, a_2, Y_1) \rightarrow \tilde{R}_-(a_2) \quad \text{and} \quad \tilde{R}_-(a_1, a_2, Y_1) \rightarrow \tilde{R}_-(a_1) \quad (28)
\]

where \(\tilde{R}_-(a)\) is given by Equation (9) and shown in Figure 4a. In other words, the two-layer medium behaves as a semi-infinite medium as the top layer becomes either optically thin or thick. This behavior suggests the definition of a reduced reflectance as,

\[
\tilde{R}^* = \frac{\tilde{R}_-(a_1, a_2, Y_1) - \tilde{R}_-(a_2)}{\tilde{R}_-(a_1) - \tilde{R}_-(a_2)} \quad (29)
\]

where \(\tilde{R}^*\) increases from 0 to 1 as \(Y_1\) varies from 0 to infinity. After combining Equations (13) and (29), the reduced reflectance can be expressed as a function of two dimensionless parameters \(\tilde{\alpha}\) and \(Y_1\),

\[
\tilde{R}^*(\tilde{\alpha}, Y_1) = \frac{\tanh(Y_1)}{1/\tilde{\alpha} + (1 - 1/\tilde{\alpha}) \tanh(Y_1)} \quad (30)
\]

where \(\tilde{\alpha}\) is given by

\[
\tilde{\alpha} = 1 + \frac{\rho_{10} + \tilde{R}_d(a_2)a_1[\rho_{10}\tilde{R}_d(a_2) + 1]}{\sqrt{a_1^2 - 1}[\rho_{10}\tilde{R}_d(a_2) - 1]} \quad (31)
\]

Figure 4b shows \(\tilde{R}^*\) as a function of \(Y_1\) for the same values of \(a_1\) and \(a_2\) used to produce Figure 4a. Unlike \(\tilde{R}_-\) showed in Figure 4a, \(\tilde{R}^*\) is nearly independent of \(a_1\) and \(a_2\). Furthermore, \(\tilde{\alpha}\)
Figure 4: (a) Diffuse reflectance of two-layer optical medium $\tilde{R}_-(a_1, a_2, Y_1)$ as a function of $Y_1$ predicted by Equation (13). Asymptotic values of $R_-(a)$ were computed from Equation (9). (b) Reduced diffuse reflectance $\tilde{R}^*$ given by Equation (29) as a function of $Y_1$ for different values of $a_1$ and $a_2$, $\rho_{01} = 0.033$ and $\rho_{10} = 0.56$. The legend applies to both Figures.

was found to be nearly constant and equal to 2.0 for $a_1$ and $a_2$ between 1.0 and 6.0 or $\omega_{tr,1}$ and $\omega_{tr,2}$ between 0.50 and 0.99. Similar results were obtained for other values of $n_1 = n_2$ between 1.00 and 2.00.

Diffuse Reflectance of a Two-Layer System - Semi-Empirical Expression

A semi-empirical approach similar to that presented above for a semi-infinite medium was applied to the two-layer medium described in Figure 1 to improve the accuracy of the two-flux approximation in predicting the diffuse reflectance of two-layer media. Results from Monte Carlo simulations presented in this section correspond to the case where $g_1 = g_2$. However, similar results hold for a given pair of $\omega_{tr,1}$ and $\omega_{tr,2}$ when $g_1$ and $g_2$ are different and regardless of their values between 0.7 and 0.9. This will be shown numerically in the following section.

Figures 5a and 5c show the diffuse reflectance $R_-$ of a two-layer system determined by Monte Carlo simulations as a function of $Y_1$ for $\omega_{tr,2} = 0.479$ and $\omega_{tr,2} = 0.958$ with $g_1 = g_2 = 0.77$, $n_1 = n_2 = 1.44$ and $\omega_{tr,1}$ ranging between 0.50 and 0.99.

The asymptotic values for smaller and larger values of $Y_1$ were calculated using Equations (25) through (27). The slope of $R_-(Y_1)$ was found to be positive for $\omega_{tr,1} > \omega_{tr,2}$ and negative otherwise. Furthermore, the slope of $R_-(Y_1)$ with respect to $Y_1$ increases as the difference between $\omega_{tr,1}$ and $\omega_{tr,2}$ increases.

Here also, a reduced reflectance $R^*$ can be defined by analogy with $\tilde{R}^*$ given by Equation
Figure 5: Diffuse reflectance $R_\perp$ predicted by Monte Carlo simulations as a function of $Y_1$ and corresponding reduced reflectance $R^*$ [Equation (32)] for $n_1 = 1.44$ and (a, b) $\omega_{tr,2} = 0.479$ and (c, d) $\omega_{tr,2} = 0.958$. Predictions of $R_\perp$ by Equations (33) and (34) are also shown (solid line).
\[ R^* = \frac{R_\alpha - R_\alpha(\omega_{tr,2})}{R_\alpha(\omega_{tr,1}) - R_\alpha(\omega_{tr,2})} \]  

Note that the predictions of the single layer diffuse reflectance by the two-flux approximation \( R_\alpha(a_1) \) and \( R_\alpha(a_2) \) are replaced by the more accurate \( R_\alpha(\omega_{tr,1}) \) and \( R_\alpha(\omega_{tr,2}) \) predicted by Equation (25). Figures 5b and 5d show the reduced reflectance \( R^* \) as a function of \( Y_1 \) for the same parameters used to produce Figures 5a and 5b, respectively. It establishes that \( R^* \) collapses onto a single curve for \( \omega_{tr,1} \) ranging between 0.50 and 0.99. In fact, no value of \( R^* \) deviates from the mean value of \( R^* \) by more than 10\% for all \( \omega_{tr,1} \).

The evolution of \( R^* \) differs significantly from \( \tilde{R}^* \) predicted by the two-flux approximation and given by Equations (30) and (31). However, Equation (30) can be used if the parameter \( \tilde{\alpha} \) is replaced by an empirical parameter \( \alpha \), i.e.,

\[ R^* = \frac{\tanh(Y_1)}{1/\alpha + (1 - 1/\alpha) \tanh(Y_1)} \]  

where \( \alpha \) was found by least squares fitting of Monte Carlo simulations for \( R^* \). A single value of \( \alpha \) was sufficient to fit the results from Monte Carlo simulations for given values of \( n_1 \) and \( \omega_{tr,2} \) and different values of \( \omega_{tr,1} \) and \( g \), i.e., \( \alpha = \alpha(n_1, \omega_{tr,2}) \). Predictions of the reduced reflectance \( R^* \) as a function of \( Y_1 \) by Equation (33) using \( \alpha = 1.104 \) are in close agreement with the more accurate Monte Carlo simulations. Thus, the diffuse reflectance of a two-layer medium can be expressed as,

\[ R_\alpha = R^*[R_\alpha(n_1, \omega_{tr,1}) - R_\alpha(n_1, \omega_{tr,2})] + R_\alpha(n_1, \omega_{tr,2}) \]  

where \( R_\alpha \) and \( R^* \) are given by Equations (25) and (33), respectively. The reconstruction of the diffuse reflectance \( R_\alpha \) from Equation (34) agrees well with predictions from Monte Carlo simulations. The primary source of disagreement lies in the 2 to 5\% relative error in \( R_\alpha(\omega_{tr,1}) \) and \( R_\alpha(\omega_{tr,2}) \) between Monte Carlo simulations and predictions by Equations (25) to (27) for \( \omega_{tr} \leq 0.70 \). For example, in Figure 5a, for \( \omega_{tr,1} = 0.479 \), the reduced diffuse reflectance predicted by Equations (33) deviate from Monte Carlo simulations by up to 6\%. On the other hand, for \( \omega_{tr,1} = 0.958 \), the predictions do not deviate by more than 2\%.

The above analysis was repeated for \( 0.50 \leq \omega_{tr,1} \leq 0.99, 0.70 \leq g_1 = g_2 \leq 0.90, \) and \( 0.50 \leq \omega_{tr,2} \leq 0.99 \) for different values of \( n_1 = n_2 \). Figure 6a shows the parameter \( 1/\alpha \) found for \( n_1 = 1.44 \) and \( 0.70 \leq g_1 = g_2 \leq 0.90 \) as a function of \( \omega_{tr,2} \). It is apparent that \( 1/\alpha \) varies slightly with \( g_1 = g_2 \) and \( \omega_{tr,1} \) for a given \( \omega_{tr,2} \). Figure 6b shows \( 1/\alpha \) as a function of \( \omega_{tr,2} \) for \( n_1 = 1.00, 1.33 \) and 1.44 and \( 0.70 \leq g_1 = g_2 \leq 0.90 \). Also shown are the following approximate polynomial expressions for \( 1/\alpha \) given by,

\[ 1/\alpha = C(n_1)\omega_{tr,2}^2 + D(n_1)\omega_{tr,2} + E(n_1) \]  

where \( C, D, \) and \( E \) depend on \( n_1 \) and are given in Table 2 for \( n_1 = 1.00, 1.33, \) and 1.44. Unlike a polynomial or other series expansion, expressing \( R^* \) by Equation (33) is well behaved in and outside the pertinent range of \( Y_1 \). It is attractive, also, because it can be estimated using the single semi-empirical parameter \( \alpha \). In other words, the diffuse reflectance of a two-layer medium, which, a priori, depends on eight parameters \( (\mu_{a,1}, \mu_{s,1}, L_1, \mu_{a,2}, \mu_{s,2}, g_1, \mu_{a,3}, \mu_{s,3}) \),
Transport single scattering albedo, $\omega_{tr,2}$

Emperical parameter, $1/\alpha$

$g_1 = 0.70$
$g_1 = 0.75$
$g_1 = 0.80$
$g_1 = 0.85$
$g_1 = 0.90$

$g_2$, and $n_1 = n_2$) was reduced to a function of only three dimensionless parameters, namely $(Y_1, \omega_{tr,1}, \alpha)$. The parameter $\alpha(n_1, \omega_{tr,2})$ provides intuitive insight into the effects of the top layer on the diffuse reflectance of the two-layer medium. Differentiating Equation (33) with respect to $Y_1$ and setting $Y_1 = 0$ yields $\alpha$, i.e., $\frac{\partial R^*}{\partial Y_1}(Y_1 = 0, \omega_{tr,1}, \omega_{tr,2}) = \alpha$. In other words, $\alpha$ is a measure of how effectively the top layer optically “shields” the semi-infinite layer. For larger $\alpha$, $R^*$ quickly progresses from $R_-(\omega_{tr,1})$ and $R_-(\omega_{tr,2})$.

For a given $\omega_{tr,2}$, $1/\alpha$ varies with $g_1 = g_2$ up to 7% about the quadratic fits. However, the reduced diffuse reflectance $R^*$ was found to be relatively insensitive to these variations. In fact, for the index matched case ($n_1 = n_0$), $1/\alpha$ can be treated as a constant equal to $1/\alpha = 0.656$. This results in difference in the predictions of $R_*$ by Equation (34) less than 0.1%.

Table 2: Regression coefficients in the expression of $1/\alpha$ given by Equation (35).

5 RESULTS AND DISCUSSION

Comparison of Model Predictions with Monte Carlo Simulations

The accuracy of Equations (33) through (35) with values of C, D, and E from Table 2 was assessed numerically for $10^{-2} \leq Y_1 \leq 6$, $0.50 \leq \omega_{tr,1} \leq 0.99$, and $0.50 \leq \omega_{tr,2} \leq 0.99$, $0.70 \leq g_1 \leq 0.90$, $0.70 \leq g_2 \leq 0.90$ and $n_1 = 1.00$, 1.33 and 1.44 for values different from those used to generate the semi-empirical model. For $Y_1$ outside of the said range, the two-layer model [Equations (25), (33) and (35)] can be replaced by the single-layer model [Equation (25)]. For comparison, an additional 10,000 Monte Carlo simulations of light transfer through the two-layer medium were performed.

Figure 7a illustrates the relative error between predictions by Equation (34) and results from Monte Carlo simulations as a function of the diffuse reflectance $R_e$ for $n_1 = 1.44$, $\omega_{tr,1} \geq 0.50$, $\omega_{tr,2} \geq 0.50$ and $Y_1 \geq 0$. Similar results were obtained for different values of $n_1$. The relative error ranged from -15% to 17%. It is evident that as the absolute value of $R_e$ decreases, the maximum relative error increases. Figure 7b shows the frequency of the relative error for $n_1 = 1.00$, 1.33, and 1.44. It is established that the relative error is similar for each index of refraction and less than 20%. Quantitatively, the mean and standard deviation of the relative error averaged over all $n_1$ are -0.16 and 1.72%, respectively. While the method performs well on average, the relative error can be larger than 10%. This is caused by two factors: (i) the inaccuracy of $1/\alpha$ [Equation (35)] in describing the two layer system and (ii) inaccuracy of Equation (25) in predicting $R_e(\omega_{tr})$. It was determined that the effects of the latter dominate over the former and that larger relative error occurs for small $\omega_{tr,1}$ and $\omega_{tr,2}$. The accuracy of Equation (25) in predicting $R_e(\omega_{tr})$ decreases for decreasing $\omega_{tr}$. This, in turn, increases the relative error in Equation (34) since $R_e$ is a function of...

![Figure 7a](image_url_a)

![Figure 7b](image_url_b)
In fact, the maximum relative error of $R_\gamma$ predicted by Equation (34) compared with Monte Carlo simulations was less than (i) 17% for $0.50 < \omega_{tr,1}$ and $0.50 < \omega_{tr,2}$, (ii) 10% for $0.60 < \omega_{tr,1}$ and $\omega_{tr,2} \geq 0.60$, (iii) 4.5% for $\omega_{tr,1}$ and $\omega_{tr,2} \geq 0.75$, and (iv) 1.5% for $\omega_{tr,1}$ and $\omega_{tr,2} \geq 0.85$.

**Reflectance of Human Skin**

This section focuses on diffuse reflectance spectroscopy of human skin as a way to demonstrate the usefulness and accuracy of the developed model. Optical properties of skin reported in the literature are summarized before predicting the spectral diffuse reflectance between 490 and 650 nm. For these wavelengths, the epidermis and the dermis have large and significantly different absorption coefficients so that human skin behaves optically as a two layer medium. In contrast, the epidermis is essentially transparent in the near infrared and the scattering albedo approaches unity [51]. Then, the present semi-empirical model is no longer valid.

The optical properties of the human skin in the visible range depend on various biological factors and can be found in the literature [4]. The epidermis is composed mainly of dead cells, keratinocytes, melanocytes, and langerhans [40]. Melanocytes synthesize melanin, the skin protein that dominates light absorption in the epidermis (Layer 1). The absorption coefficient of the epidermis $\mu_{a,1}(\lambda)$ can be expressed as [52],

$$\mu_{a,1}(\lambda) = \mu_{a,mel} f_{mel} + (1 - f_{mel}) \mu_{a,back}$$ \hspace{1cm} (36)

where $f_{mel}$ is the volume fraction of melanocytes in the epidermis and $\mu_{a,back}(\lambda)$ is the background absorption of human flesh given by [52,53],

$$\mu_{a,back}(\lambda) = 7.84 \times 10^8 \lambda^{-3.255}$$ \hspace{1cm} (37)

Furthermore, the absorption coefficient of a single melanocytes as a function of wavelength has been approximated as [54],

$$\mu_{a,mel}(\lambda) = 6.60 \times 10^{11} \lambda^{-3.33}$$ \hspace{1cm} (38)

Here $\lambda$ is expressed in nm and $\mu_{a,back}(\lambda)$ and $\mu_{a,mel}(\lambda)$ are in cm$^{-1}$.

The absorption coefficient of the dermis (Layer 2) is determined primarily by the absorption of blood [55,56] and can be written as [51,57],

$$\mu_{a,2}(\lambda) = f_{blood}\mu_{a,blood}(\lambda) + (1 - f_{blood}) \mu_{a,back}(\lambda)$$ \hspace{1cm} (39)

where $f_{blood}$ is the volume fraction of the dermis occupied by blood. Visible light absorption by blood is dominated by the presence of oxyhemoglobin and deoxyhemoglobin so that $\mu_{a,blood} = \mu_{a,oxy} + \mu_{a,deoxy}$. The absorption coefficient of oxyhemoglobin is given by [51,57],

$$\mu_{a,oxy}(\lambda) = \epsilon_{oxy}(\lambda)C_{heme}SO_2/66,500$$ \hspace{1cm} (40)

where $\epsilon_{oxy}$ is the molar extinction coefficient of oxyhemoglobin [in cm$^{-1}$/(mole/L)] with molecular weight of 66,500 g/mole, $C_{heme}$ is the concentration ratio of hemoglobin in blood.
[g/L], and $SO_2$ is the oxygen saturation defined as the mass ratio of oxyhemoglobin to total hemoglobin ($0 \leq SO_2 \leq 100\%$) [20]. Similarly, the absorption coefficient of deoxyhemoglobin is given by [51,57],

$$\mu_{a,\text{deoxy}}(\lambda) = \epsilon_{\text{deoxy}}(\lambda)C_{\text{heme}}(1 - SO_2)/66,500$$

(41)

where $\epsilon_{\text{deoxy}}$ is the molar extinction coefficient of deoxyhemoglobin. Unlike the blood volume $f_{\text{blood}}$ and oxygen saturation $SO_2$ which may vary from location to location and with metabolic state, the average value of $C_{\text{heme}} = 150$ g/L is typically used [51,58,59]. Furthermore, the molar extinction coefficients of oxy- and deoxy- hemoglobin for a wide range of wavelengths are available in the literature [51,60–63] and reproduced in Figure 8 in the visible range 450 to 700 nm.

![Figure 8: Spectral molar extinction coefficient of human oxy- and deoxy- hemoglobin in the visible range (480 to 700 nm) [51].](image)

The transport scattering coefficient of biological media has been shown to follow a power law dependence on wavelength [64],

$$\mu_{s,\text{tr}} = C_{\text{tr}}\lambda^k$$

(42)

where $\lambda$ is expressed in nm and $\mu_{s,\text{tr}}$ in cm$^{-1}$. For both epidermis and dermis, the values of $C_{\text{tr}}$ and $k$ were taken as $5.50 \times 10^5$ cm$^{-1}$ and −1.30, respectively [65]. The thickness of the epidermis on the hand and arm ranges between 50 and 130 $\mu$m [66]. The blood volume fraction and melanocyte volume fraction range from 0.2 to 7% and from 1 to 43%, respectively [52]. In this simulation, the epidermal thickness was taken as $L_1 = 100$ $\mu$m. The epidermis and dermis were assumed to have the same index of refraction equal to 1.44 [24]. The blood volume and melanin concentrations were taken as $f_{\text{blood}} = 2.5\%$ and $f_{\text{mel}} = 1.0\%$ which are typical of healthy, lightly pigmented human skin [52].
Figure 9 shows the diffuse reflectance of human skin for $SO_2 = 0$ and 100% as predicted by Monte Carlo simulations and Equations (33) through (35) as a function of wavelength.

![Figure 9: Comparisons of diffuse reflectance of skin predicted by Monte Carlo simulations and by Equation (34) as a function of wavelength for $f_{mel} = 1.0\%$, $f_{blood} = 2.5\%$, $L_{epi} = 100\, \mu m$ and $SO_2 = 0$ and 100%.

For high values of $SO_2$, i.e., for highly oxygenated blood, the skin exhibits the absorption peaks of oxyhemoglobin around 542 and 580 nm. For low $SO_2$, or oxygen depleted blood, the skin exhibits the single absorption peak of deoxyhemoglobin near 560 nm. In both cases, the semi-empirical model developed in this study agrees with Monte Carlo simulations within less than 8% relative error. The relative error is less than 3% for wavelength between 525 and 600 nm where absorption by oxy- and deoxy-hemoglobin is most distinct. Thus, the model can be used in diffuse reflectance spectroscopy for monitoring oxygenation and microcirculation of skin and wound.

Figure 10 shows in-vivo diffuse reflectance measurements from the top of the index finger of a healthy, Caucasian male subject along with a reconstruction of the same reflectance spectrum by the present model [Equations (33) through (35) and Equations (36) through (42)]. The reflectance spectrum was measured using a FDA approved hyperspectral camera (OxyVu, HyperMed Inc., Burlington MA). The reconstruction was performed by minimizing the root mean square error between the observed and reconstructed diffuse reflectance while varying $f_{mel}$, $f_{blood}$, $SO_2$, and $L_1$. The Levenberg-Marquardt algorithm [67] was used to perform the non-linear fit. The best-fit parameters found were $f_{mel} = 1.03\%$, $f_{blood} = 2.79\%$, and $SO_2 = 29.0\%$ and $L_1 = 66\, \mu m$. The $SO_2$ value predicted by the present method is in close agreement with the measurement obtained with OxyVu (28%) [20]. Furthermore, the retrieved value of $f_{mel}$ was consistent with that of Caucasian skin [52] and the estimate of $f_{blood}$ and $L_{epi}$ fell within the range of physiologically realistic values [52, 66]. Details discussion of the capability and robustness of inverse method using the semi-empirical model.
diffuse skin reflectance, $R = \frac{\text{Measured reflectance}}{\text{Reconstructed reflectance}}$

Figure 10: Experimentally measured diffuse reflectance from the top of the index finger of a healthy, Caucasian subject along with reconstructed reflectance predicted by Equations (33) through (35) and Equations (36) through (42) with best fit parameters $f_{\text{mel}} = 1.03\%$, $f_{\text{blood}} = 2.79\%$, $SO_2 = 29.0\%$ and $L_1 = 66 \mu m$.

developed in this paper paper and application to hyperspectral imaging of human skin will be reported in a subsequent publication.

6 CONCLUSION

A model of diffuse reflectance was developed for non-emitting, absorbing, and scattering semi-infinite and two-layer media. Scattering was assumed to be strongly forward and to dominate over absorption. First, the two-flux approximation was used to find an approximate expression for the diffuse reflectance of semi-infinite medium. Then, the coefficients of the expression were modified with numerical data from Monte Carlo simulations resulting in a semi-empirical model. Predictions from the semi-empirical model agree with results from Monte Carlo simulations within 10\% for $\omega_{tr} > 0.50$. This relative error decreases to less than 2\% for $\omega_{tr} > 0.70$.

Similarly, an approximate reflectance $\tilde{R}_{\infty}$ and reduced reflectance $\tilde{R}^*$ were derived from the two-flux approximation of a two-layer medium. It was shown that $\tilde{R}^*$ is a function of the two-flux optical thickness $Y_1$ and parameter $\tilde{\alpha}$. To account for phenomena taking place at the medium/air interface, $\tilde{\alpha}$ was replaced by an empirical parameter $\alpha$ which was fitted to match results from Monte Carlo simulations. Therefore, the reflectance of the two-layer medium could be expressed as a function of a single empirical parameter. The diffuse reflectance predicted by the semi-empirical model fell within 10\% of results from Monte Carlo simulations for $0.60 < \omega_{tr,1}$ and $0.60 < \omega_{tr,2}$ and the different values of $n_1$ and $\tau_1$ considered

20
in this study.

Finally, the semi-empirical model for two-layer media was applied to lightly pigmented human skin with properties taken from the literature. The model developed in this study agrees with Monte Carlo simulations within 3% relative error for wavelengths between 480 and 650 nm.

**NOMENCLATURE**

$a, b$  
K-M dimensionless parameters

$A_i, B_i$  
Single layer model fit coefficients

$C, D, E$  
Two layer fit coefficients

$C_{tr}$  
Scattering constant in Equation (42)

$F^-, F^+$  
Diffuse backward and forward fluxes, W/cm$^2$-nm

$g$  
Henyey-Greenstein asymmetry factor

$I$  
Radiation intensity, W/cm$^2$-sr-nm

$I_0$  
Incident radiation intensity at the slab surface, W/cm$^2$-sr-nm

$I_r$  
Intensity of reflected light, W/cm$^2$-sr-nm

$k$  
Scattering constant in Equation (42)

$K$  
K-M effective absorption coefficient, 1/cm

$L_1$  
Thickness of slab layer, cm

Back-scattered radiative flux, W/cm$^2$-nm

$r$  
Position vector, cm

$R$  
Diffuse reflectance

$R^*$  
Reduced reflectance

$s$  
Unit vector in a given direction

$S$  
K-M effective scattering coefficient, 1/cm

$SO_2$  
Oxygen saturation, %

$Y$  
K-M optical thickness

$z$  
Distance into the medium surface, cm

**Greek symbols**

$\alpha$  
Empirical fit coefficient of the two layer reflectance model

$\beta$  
Total extinction coefficient, 1/cm

$\eta, \chi$  
Parameters defined by Equation (15)

$\theta$  
Polar angle, rad

$\theta_i$  
Angle of incidence on interface, rad

$\theta_t$  
Angle of transmitted radiation through interface, rad

$\theta_c$  
Critical angle for total internal reflection, rad

$\phi$  
Parameter defined by Equations (17)

$\Phi$  
Scattering phase function, sr$^{-1}$
\( \mu \) Director cosine, \( \mu = \cos \theta \)
\( \mu_a \) Linear absorption coefficient, \( 1/\text{cm} \)
\( \mu_s \) Linear scattering coefficient, \( 1/\text{cm} \)
\( \mu_{s, tr} \) Transport scattering coefficient (\( = \mu_s(1-g) \), \( 1/\text{cm} \))
\( \omega \) Single scattering albedo
\( \omega_{tr} \) Transport single scattering albedo
\( \Omega \) Solid angle, sr
\( \rho_{01} \) Specular reflectivity to normally incident light
\( \rho_{10} \) Hemispherical-hemispherical reflectivity
\( \rho''(\theta_i) \) Directional specular reflectivity
\( \tau_{tr,1} \) Transport optical thickness of the slab layer

Subscripts
1 Refers to layer 1
2 Refers to layer 2
\( \lambda \) Wavelength
\( = \) Refers to two-layer medium
\( - \) Refers to semi-infinite medium
\( \text{back} \) Background
\( \text{deoxy} \) Dexyhemoglobin
\( d \) Hemispherical-hemispherical reflectance with index matched boundary
\( \text{oxy} \) Oxyhemoglobin
