An 8-day-old female presented with abdominal distension, anuria and a translucent membrane protruding from the vagina. Clinical examination revealed a palpable abdomino-pelvic fluctuant mass lesion. On perineal examination, a translucent bulge was seen and increased in size when the neonate cried or when pressure was exerted on the abdominal mass (Figure 1). Differential diagnoses considered were imperforate hymen, urethral prolapse and prolapsed ureterocele. Ultrasound of the abdomen revealed a large abdomino-pelvic cystic mass lesion containing mobile internal debris (Figure 2). Bilateral moderate hydrenephrosis was also seen. Diagnosis of imperforate hymen causing hydrometrocolpos, anuria and bilateral hydrenephrosis was made.

The bulging membrane was incised and drained 300 mL of fluid. The child improved symptomatically. Hydrenephrosis resolved on follow-up ultrasonography. An imperforate hymen causing hydrometrocolpos, bilateral hydrenephrosis and associated anuria/urinary retention is extremely rare in the neonatal period.1 Neonatal Hydrometrocolpos secondary to imperforate hymen usually presents soon after birth with a lower abdominal mass and a bulging introitus. Other reported presentations include acute renal failure, respiratory distress, sepsis, and intestinal obstruction.2 Sonographic findings include cystic abdomino-pelvic mass containing debris with posterior acoustic enhancement and hydroosalpinx.3 Hymenectomy through perineal approach is the mainstay of management.1
