SUMMARY
An asymptotic method, valid in the presence of smoothly varying heterogeneity, is used to derive a semi-analytic solution to the equations for fluid and solid displacements in a poroelastic medium. The solution is defined along trajectories through the porous medium model, in the manner of ray theory. The lowest order expression in the asymptotic expansion provides an eikonal equation for the phase. There are three modes of propagation, two modes of longitudinal displacement and a single mode of transverse displacement. The two longitudinal modes define the Biot fast and slow waves which have very different propagation characteristics. In the limit of low frequency, the Biot slow wave propagates as a diffusive disturbance, in essence a transient pressure pulse. Conversely, at low frequencies the Biot fast wave and the transverse mode are modified elastic waves. At intermediate frequencies the wave characteristics of the longitudinal modes are mixed. A comparison of the asymptotic solution with analytic and numerical solutions shows reasonably good agreement for both homogeneous and heterogeneous earth models.

1 INTRODUCTION
Due to advances in subsurface monitoring, there is an increased recognition of the importance of coupled fluid flow and deformation within the Earth. For example, recent studies highlight the role of pressure changes and associated deformation in observed time-lapse seismic anomalies below, within, and above a producing reservoir (Guilbot & Smith 2002; Landro & Stammeijer 2004; Hatchell & Bourne 2005; Tura et al. 2005; Hawkins et al. 2007; Hodgson et al. 2007; Rickett et al. 2007; Roste et al. 2007; Schutjens et al. 2007; Staples et al. 2007). These studies document both changes in layer position and thickness as well as seismic velocity changes due to stress variations. Such observations support conventional geodetic measurements of overburden deformation due to injection and production (Castle et al. 1969; Colazas & Strehle 1994) as well as newer satellite-based data (Fielding et al. 1998; Standliffe & van der Kooij 2001) and also downhole tiltmeter data (Du et al. 2005; Maxwell et al. 2008). Furthermore, deformation of the overburden has been used to infer pressure changes and flow properties within producing reservoirs. For example, Vasco & Ferretti (2005) used satellite-based Interferometric Synthetic Aperture Radar (InSAR) measurements to image pressure changes, and ultimately permeability variations. Using a similar technique Hodgson et al. (2007) used time-lapse 3-D seismic data to image pressure changes in a deep-water reservoir in the Gulf of Mexico.

The growing emphasis on geophysical monitoring and the continuing development of time-lapse seismic and geodetic technology create a need for efficient techniques for modelling coupled fluid flow and deformation. At present, the literature on coupled modelling of fluid flow and geomechanics is vast but lacking in some respects. One difficulty follows from the complexity of modelling fully general coupled deformation and flow. Simply modelling fluid flow is a significant undertaking with a large number of processes to consider, such as multiphase flow, chemical transport and pressure-dependent flow properties (Bear 1972; Peaceman 1977; de Marsily 1986; Wu & Pruess 2000). And the modelling of deformation can involve elastic deformation, plastic flow, faulting and fracturing, as well as pressure and stress dependent moduli (Coussy 2004; Showalter & Stefanelli 2004; Jaeger et al. 2007). In this paper, I will narrow the focus to coupled elastic deformation and single phase flow. Furthermore, the elastic moduli will be assumed to be time invariant. Even with these restrictions, the problem is a difficult one (Showalter 2000; Wang 2000), and there is a need for general, yet efficient, methods for poroelastic modelling.

Typically, there has been a trade-off between generality and efficiency in the modelling of coupled poroelastic processes. Much of the prior analytic work on both quasi-static and dynamic poroelastic modelling has been concerned with homogeneous media (Rice & Cleary 1976; Segall 1985; Booker & Carter 1986, 1987; Rudnicki 1986; Lo et al. 2006; Pride 2005). The next level of complexity involves analytic models for poroelastic modelling in layered (Wang & Kumpel 2003) and 1-D (Simon et al. 1984; Gajo & Mongiovì 1995) media. Though the resulting 1-D solutions are complete, they involve special functions and/or numerical integration and are thus difficult to interpret. The majority of work on full 3-D heterogeneous media is based upon purely numerical techniques, such
as finite elements, finite difference and boundary-elements (Noori-shad et al. 1984; Chang et al. 1991; Lewis & Sukirman 1993; Lewis & Ghafori 1997; Gutierrez & Lewis 2002; Rutqvist et al. 2002; Minkoff et al. 2003, 2004; Dean et al. 2006; Masson et al. 2006), which, while general, do not scale well with problem size and do not provide great insight into the nature of poroelastic propagation. Furthermore, the significantly different velocities, and hence timescales, associated with diffusive and elastic propagation, makes it difficult to model the coupled processes accurately and efficiently using numerical methods.

This paper occupies the middle-ground between the analytic and the numerical work of previous studies. Here I develop a semi-analytic solution which is valid in a medium with smoothly varying heterogeneity of arbitrarily large magnitude. The approach, based upon an asymptotic solution to the equations governing deformation and flow in a poroelastic medium, is related to ray-based techniques for modelling wave propagation (Friedlander & Keller 1955; Kline & Kay 1979; Jeffrey & Kawahara 1982; Kravtsov & Orlov 1990; Anile et al. 1993; Bouche et al. 1997; Korsunsky 1997; Chapman 2004; Vasco 2007). The asymptotic expansion follows from the application of the method of multiple scales and is appropriate for modelling propagation in a medium with regions of smoothly varying properties separated by sharp boundaries (Jeffrey & Taniuti 1964; Anile et al. 1993). The technique differs from a straightforward expansion in powers of frequency (Friedlander & Keller 1955; Keller & Lewis 1995; Chapman 2004) and from an expansion in the scale parameter of the poroelastic convolution operator (Hanyga & Seredyńska 1999a,b). One advantage of this methodology is its ability to model propagation over a broad range of frequencies and to represent behaviour from diffusive to hyperbolic propagation (Vasco 2007). Furthermore, this technique is very general and applicable to the modelling of non-linear behaviour (Jeffrey & Kawahara 1982; Anile et al. 1993), such as that due to multiphase flow (Vasco 2004) and pressure-dependent moduli (Vasco 2009).

2 METHODOLOGY

2.1 The governing equations

I begin with the equations governing the evolution of the displacement fields of the solid grains \( \mathbf{u}_s \) and a fluid \( \mathbf{u}_f \) which are functions of the spatial coordinates \( \mathbf{x} \) and time \( t \) that follow from Biot’s fundamental work (Biot 1956, 1962). These equations are the consequence of a long history of work on deformation in a fluid saturated solid (de Boer 2000). There is some advantage in considering alternative coordinates: the solid grain displacement \( \mathbf{u} = \mathbf{u}_s - \mathbf{u}_f \) and the differential fluid displacement \( \mathbf{w} = \mathbf{u}_f \). Using these variables one can write the Biot equations for a fluid-saturated porous medium as

\[
\nabla \cdot \mathbf{r} - \nabla p_t = \rho \frac{\partial^2 \mathbf{u}}{\partial t^2} + \rho \frac{\partial^2 \mathbf{w}}{\partial t^2}
\]

\[
-\nabla p_t = \rho \frac{\partial^2 \mathbf{u}}{\partial t^2} + \eta \frac{\partial}{\partial t} \left( \frac{\mathbf{w}}{K} \right),
\]

where \( \mathbf{r} \) is the deviatoric stress tensor, related to the displacement of the solid grains by the equation (Pride 2005)

\[
\mathbf{r} = G \left( \nabla \mathbf{u} + \nabla \mathbf{u}^\mathbf{r} - \frac{2}{3} \nabla \cdot \mathbf{u} \mathbf{I} \right),
\]

where \( G \) is the shear modulus of the porous framework and \( \mathbf{I} \) is the identity matrix with ones along the diagonal and zeros elsewhere. In the expression for the deviatoric stress tensor (3) I have employed the dyadic notation in which \( \nabla \mathbf{u} \) is given by the outer product of the two vectors

\[
\nabla \mathbf{u} = \begin{pmatrix} \nabla u_x \\ \nabla v_y \\ \nabla w_z \end{pmatrix} = \begin{pmatrix} u_x \mathbf{i} \\ v_y \mathbf{j} \\ w_z \mathbf{k} \end{pmatrix}
\]

which can be thought of as a matrix (Spiegel 1959) and \((\nabla \mathbf{u})^T\) is the transpose of this matrix. The density of the solid matrix and the pore fluid are given by \( \rho \) and \( \rho_f \), respectively, while the fluid viscosity and permeability are denoted by \( \eta \) and \( k(\mathbf{x}) \). The average total pressure, the ‘confining pressure’, \( p_c(\mathbf{x}, t) \), is given by the sum of the divergence of the solid displacements and the fluid displacements

\[
p_c = - (K_s \nabla \cdot \mathbf{u} + C \nabla \cdot \mathbf{w}), \quad (4)
\]

similarly for the fluid pressure, \( p_f \),

\[
p_f = - (C \nabla \cdot \mathbf{u} + M \nabla \cdot \mathbf{w}), \quad (5)
\]

where \( K_s(\mathbf{x}) \) is the undrained bulk modulus, \( C(\mathbf{x}) \) and \( M(\mathbf{x}) \) are spatially varying moduli defined by Biot (1962). The modulus \( M \) is known as the fluid-storage coefficient (Pride 2005) and represents the amount of fluid which can assimilate in a sample at constant volume. It is the poroelastic modulus most directly involved in fluid pressure diffusion. The modulus \( C \) is associated with the coupling between the fluid pressure and the elastic deformation of the solid matrix, referred to as Biot’s coupling modulus.

There are numerous ways of expressing the various moduli characterizing a poroelastic medium (Wang 2000). I shall merely quote Pride’s (2005) expressions for \( K_s \), \( C \) and \( M \) in terms of the medium porosity \( \phi \), the drained bulk modulus \( K_d \), the bulk modulus of the solid grains composing the porous medium \( K_s \) and the bulk modulus of the fluid \( K_f \),

\[
K_u = \frac{K_d + [1 - (1 - \phi)K_d/K_s]K_f/\phi}{1 + \Delta}, \quad (6)
\]

\[
C = \frac{(1 - K_d/K_s)K_f}{(1 + \Delta)\phi}, \quad (7)
\]

and

\[
M = \frac{K_f}{(1 + \Delta)\phi}, \quad (8)
\]

where \( \Delta \) is a dimensionless parameter

\[
\Delta = \frac{1 - \phi K_f}{\phi K_s} \left[ 1 - \frac{K_d}{K_s (1 - \phi) K_f} \right], \quad (9)
\]

which is always small. The above relationships follow from the work of Biot & Willis (1957) and Gassmann (1951), and are thus known as the ‘Biot–Gassmann’ relations (Pride 2005). The relationships (6), (7), (8) and (9) enable one to express the parameters \( K_u \), \( C \) and \( M \) in terms of more commonly measured quantities. Note that the parameter \( C \), which couples the fluid pressure and the elastic displacements (eq. 5), vanishes when the drained bulk modulus \( K_d \) equals the bulk modulus of the solid grains \( K_s \).

There is another useful way to express the moduli in terms of two other parameters, Skempton’s coefficient \( B \) and the Biot–Willis constant \( a \). The Biot–Willis constant is related to the ratio of the compressibility of the mineral grains to the compressibility of the rock sample and is always of order 1 (Zimmerman 2000). Skempton’s
coefficient is approximately the ratio of the compressibility of the pores to the compressibility of the pore fluid and generally lies between 0 and 1. One can express both $C$ and $M$ in terms of $K_u$, $B$ and $\alpha$,

$$C = BK_u$$

(10)

and

$$M = \frac{BK_u}{\alpha}.$$  

(11)

The product $\alpha B$ is a poroelastic coupling parameter which indicates if one may neglect geomechanical effects when computing fluid pressure (Zimmerman 2000)

$$\alpha B = 1 - \frac{K_d}{K_u}. \quad (12)$$

If $\alpha B$ is small one may generally neglect the coupling between the deformation of the solid matrix when modelling fluid pressure propagation (Zimmerman 2000).

In eq. (2), I have assumed that the permeability, $k(x)$ is only a function of spatial position, independent of time. In more general formulations $k$ also varies with time and the term on the right-hand side of eq. (2) is actual a convolution between $1/k$ and $w$ (Hanyga & Seredyńska 1999a,b; Pride 2005). The approach outlined here will work for such a general formulation, though the low frequency approximation given later must be modified to account for the frequency behaviour of $K$. This more general formulation is easier to represent by transforming the governing equations into the frequency domain by taking the Fourier or Laplace transform (Bracewell 1978) of eqs (1) and (2),

$$\nabla \cdot \mathbf{T} - \nabla P_t + \omega^2 \rho \mathbf{U} + \omega^2 \rho_1 \mathbf{W} = 0$$

(13)

$$-\nabla P_t + \omega^2 \rho_1 \mathbf{U} + i \omega \frac{\eta}{K} \mathbf{W} = 0,$$  

(14)

where the capital letters denote the Fourier transforms of the respective quantities and $K$ may now be a function of the frequency $\omega$. Thus, $U(x, \omega)$ is the Fourier transform of $u(x, t)$, a function of frequency and similarly for $W(x, \omega)$, $T(x, \omega)$, $P_t(x, \omega)$, $P_i(x, \omega)$ and $K(x, \omega)$. Applying the Fourier transform to eqs (3), (4) and (5) I can write the governing eqs (13) and (14) solely in terms of $U$ and $W$

$$\nabla \left[ G \left( \nabla \mathbf{U} + \nabla \mathbf{U}^* - \frac{2}{3} \nabla \cdot \mathbf{U} \right) \right] + \nabla \left( K_u \nabla \cdot \mathbf{U} + C \nabla \cdot \mathbf{W} \right) + \omega^2 \rho \mathbf{U} + \omega^2 \rho_1 \mathbf{W} = 0$$

(15)

$$\nabla \left( C \nabla \cdot \mathbf{U} + M \nabla \cdot \mathbf{W} \right) + \omega^2 \rho_1 \mathbf{U} + i \omega \frac{\eta}{K} \mathbf{W} = 0.$$  

(16)

### 2.2 An asymptotic solution for deformation and flow

Due to the presence of spatially varying coefficients in eqs (15) and (16) it is not possible to derive an analytic solution. However, using an asymptotic approach I can derive a semi-analytic solution which is valid in the presence of smoothly varying heterogeneity of arbitrarily large magnitude. The approach, known as the method of multiple scales, relies on a separation of scales (Anile et al. 1993; Kevorkian & Cole 1996). In this case, I assume that the heterogeneity varies at a scale length, denoted by $L$, which is much larger than the scale length over which the solid displacement and fluid pressure jump from their initial or background values to the new values after a poroelastic disturbance passes, denoted by $l$. Thus, $l \ll L$ and the ratio $\varepsilon = l/L$ is much smaller than 1. In the method of multiple scales one considers the problem on a spatial scale comparable to $\varepsilon$, transforming the problem to new spatial variables $X$, where

$$X = \varepsilon x$$

(17)

are referred to as the ‘slow’ coordinates. Also, the solutions to eqs (15) and (16) are represented as power series in $\varepsilon$

$$U(X, \omega, \theta) = e^{i \theta} \sum_{l=0}^{\infty} \varepsilon^l U_l(X, \omega)$$

(18)

and

$$W(X, \omega, \theta) = e^{i \theta} \sum_{l=0}^{\infty} \varepsilon^l W_l(X, \omega),$$

(19)

where $\theta(x, \omega)$ is a function, referred to as the phase, related to the kinematics of the propagating disturbance. Because $\varepsilon$ is small, less then 1, only the first few terms of these power series are significant. The series (18) and (19) are in the form of generalized plane wave expansions of $U(X, \omega, \theta)$ and $W(X, \omega, \theta)$, similar to that used in modelling electromagnetic and elastic waves (Luneburg 1966; Kline & Kay 1979; Aki & Richards 1980; Kravtsov & Orlov 1990). The variable $\theta(X, \omega)$ is known as the phase and is associated with the traveltime of the disturbance.

I consider $U$ and $W$ to be functions of the slow coordinates $X$ and as a consequence the derivatives contained in the differential operators need to be written in terms of $X$ and not in terms of $x$. Using the chain rule, the derivatives may be rewritten as

$$\frac{\partial U}{\partial x_i} = \frac{\partial X_j}{\partial x_i} \frac{\partial U}{\partial X_j} + \frac{\partial \theta}{\partial x_i} \frac{\partial U}{\partial \theta}$$

(20)

and hence, making use of eq. (17),

$$\frac{\partial \varepsilon}{\partial x_i} = \frac{\partial \theta}{\partial \theta} \frac{\partial \varepsilon}{\partial \theta}.$$  

(21)

Thus, the differential operators, which are defined in terms of the partial derivatives with respect to the spatial coordinates, are likewise rewritten as

$$\nabla U = \varepsilon \nabla_X U + \nabla \theta \frac{\partial U}{\partial \theta}$$

(22)

$$\nabla \cdot U = \varepsilon \nabla_X \cdot U + \nabla \theta \cdot \frac{\partial U}{\partial \theta},$$

(23)

where $\nabla_X$ denotes the gradient with respect to the components of the slow variable $X$.

The asymptotic solution of eqs (15) and (16) is obtained by writing the differential operators in terms of $X$ and $\theta$ and substituting the power series (18) and (19) for $U$ and $W$, respectively. The two equations that result contain infinite sequences of terms, each containing $\varepsilon$ to a particular power. Because $\varepsilon$ is assumed to be small, only the terms of lowest order in $\varepsilon$ are retained. In the next two subsections, I shall consider expressions containing terms of order $\varepsilon^0 \sim 1$ and $\varepsilon^1$. In the discussion that follows, I shall suppress the subscripts on the gradient operators, that is I shall write $\nabla$ in place of $\nabla_X$ in order to streamline the equations. It should be understood that all operators applied to $U$ and $W$ are with respect to the slow coordinates $X$.
2.2.1 Terms of order $\varepsilon^0 \sim 1$: an expression for the phase

The full complement of terms up to order $\varepsilon$ is given in Appendix A, eqs (A8) and (A12). If I only consider terms or order $\varepsilon^0 \sim 1$, I obtain

$$G \nabla \theta \cdot \frac{\partial^2 U}{\partial \theta^2} + G \nabla \theta \nabla \theta \cdot \frac{\partial^2 U}{\partial \theta^2} - \frac{2}{3} G \nabla \theta \cdot \frac{\partial^2 U}{\partial \theta^2} + K_u \nabla \theta \nabla \theta \cdot \frac{\partial^2 U}{\partial \theta^2} + \omega^2 \rho U_0 + C \nabla \theta \nabla \theta \cdot \frac{\partial^2 W}{\partial \theta^2} + \omega^2 \rho W_0 = 0$$

(24)

and

$$C \nabla \theta \nabla \theta \cdot \frac{\partial^2 U}{\partial \theta^2} + \omega^2 \rho_I U_0 + M \nabla \theta \nabla \theta \cdot \frac{\partial^2 W}{\partial \theta^2} + \omega^2 \rho W_0 = 0,$$  

(25)

where

$$\rho = \frac{\omega}{\omega K}.$$  

(26)

In these equations, I have substituted in the power series expansions (18) and (19). Due to the specific form of the dependence of $U$ and $W$ on the phase, the derivatives with respect to $\theta$ are given by

$$\frac{\partial U}{\partial \theta} = iU$$  

(27)

$$\frac{\partial W}{\partial \theta} = iW$$  

(28)

and similarly for higher-order derivatives. Also, let the vector $p$ denote the gradient of $\theta$

$$p = \nabla \theta,$$  

(29)

the gradient vector of the phase function. Substituting for the derivatives with respect to $\theta$ and for $\nabla \theta$ in eqs (24) and (25), I obtain equations for $U_0$ and $W_0$

$$\beta pp \cdot U_0 - \alpha U_0 + C pp \cdot W_0 - \omega^2 \rho_I W_0 = 0$$  

(30)

and

$$C pp \cdot U_0 - \omega^2 \rho_I U_0 + M pp \cdot W_0 - \omega^2 \rho W_0 = 0,$$  

(31)

where

$$\beta = K_u + \frac{1}{3} G$$  

(32)

and

$$\alpha = \omega^2 \rho - G p^2.$$  

(33)

[see Appendix A, eqs (A14) and (A15)]. I can write eqs (30) and (31) in matrix form

$$
\begin{pmatrix}
\alpha I - \beta pp \cdot I - \omega^2 \rho_I I - C pp \cdot I
\omega^2 \rho_I I - C pp \cdot I
\end{pmatrix}
\begin{pmatrix}
U_0
W_0
\end{pmatrix}
= \begin{pmatrix} 0 \\ 0 \end{pmatrix}.
$$

(34)

From linear algebra it is known that the system of eqs (34) has a non-trivial solution if and only if the determinant of the coefficient matrix vanishes (Noble & Daniel 1977). The vanishing of the determinant defines a polynomial equation in the components of the vector $p$ with coefficients which are functions of the medium parameters. From the definition of $p$, eq. (29), one finds that the vanishing of the determinant also defines a non-linear partial differential equation for $\theta(X, \omega)$, the eikonal equation associated with propagation in a poroelastic medium (Kravtsov & Orlov 1990). While it is possible to form the polynomial equation directly from the determinant of the coefficient matrix of eq. (34), I follow a less direct route, avoiding some rather tedious algebra.

The approach I take works with the eigenvalues and eigenvectors associated with the coefficient matrix in eq. (34). There is a connection between the eigenvalues of the coefficient matrix and the determinant of the coefficient matrix. Specifically, the product of the eigenvalues, an invariant of the coefficient matrix, equals the determinant (Noble & Daniel 1977). In this approach, I first observe that the vectors

$$e = \left[ \begin{array}{c} y_1 p \\ y_2 p \end{array} \right],$$  

(35)

and

$$e^+ = \left[ \begin{array}{c} y_1 p^+ \\ y_2 p^+ \end{array} \right],$$  

(36)

where $y_1$ and $y_2$ are scalar coefficients and $p^+$ denotes a vector perpendicular to $p$, look like candidate eigenvectors of the system of eqs (34). That is, vectors which satisfy the equation

$$\Gamma e = \lambda e,$$  

(37)

where $\Gamma$ is the coefficient matrix in (34) and $\lambda$ is a scalar to be determined. A similar equation holds for for $e^+$ with a different scalar, which I will denote by $\lambda^+$. From eq. (29) one observes that the vector $p$ is perpendicular to the phase front, the iso-surface of constant phase while $p^+$ lies within the plane tangent to the iso-surface. These vectors denote longitudinal and transverse modes of propagation and, as I shall show, propagate with differing velocities. As such, I consider each mode separately, first examining deformation in the direction of $p$, the longitudinal displacement vector.

**Longitudinal displacements**

If I substitute the vector $e$, defined in (35) into the eigenvalue eq. (37), where the matrix $\Gamma$ is given by the matrix in (34), I find that

$$[ (\alpha - \beta p^2) y_1 + (\omega^2 \rho_I - C p^2) y_2 ] p = \lambda y_1 p,$$  

(38)

$$[ (\omega^2 \rho_I - C p^2) y_1 + (\omega^2 \rho - M p^2) y_2 ] p = \lambda y_2 p.$$  

(39)

where $p^2 = p \cdot p$ is the square of the magnitude of the vector $p$. I may write eqs (38) and (39) as a single matrix equation

$$\begin{pmatrix}
\alpha - \beta p^2 - \lambda \\
\omega^2 \rho_I - C p^2 \\
\omega^2 \rho - M p^2 - \lambda
\end{pmatrix}
\begin{pmatrix}
y_1 \\
y_2 \\
0
\end{pmatrix}
= \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}.$$  

(40)

for $y_1$ and $y_2$. As noted above, this equation has a non-trivial solution if and only if the determinant of the coefficient matrix vanishes. This is a polynomial equation containing the medium parameters, $p$, and $\lambda$. Now, the medium parameters are assumed to be fixed but $p$ and $\lambda$ may both be considered as unknowns in the polynomial. Thus, there is some freedom in specifying the values of $\lambda$ and $p$. I take advantage of this flexibility and set $\lambda$ equal to zero in order to simplify the expression for the determinant and obtain an equation solely in terms of $p$

$$\det\left(\begin{array}{cc}
\alpha - \beta p^2 & \omega^2 \rho_I - C p^2 \\
\omega^2 \rho_I - C p^2 & \omega^2 \rho - M p^2
\end{array}\right)
= (\alpha - \beta p^2)(\omega^2 \rho - M p^2) - (\omega^2 \rho_I - C p^2)^2 = 0.$$  

(41)

Eq. (41) is a quadratic equation for $p^2$

$$p^2 - \frac{\omega^2(\rho M + p H - 2 \rho_0 C)}{(H M - C^2)} p^2 + \frac{\omega^4(\rho_0 \rho - \rho_0^2)}{(H M - C^2)} = 0.$$  

(42)
where $H$ is given by

$$H = K_o + \frac{4}{3} G.$$  

(43)

The quadratic eq. (42) has the solution

$$p^2 = \frac{\omega^2}{2} \left[ \gamma \pm \sqrt{\gamma^2 - \frac{4(\rho \hat{\rho} - \rho C^2)}{HM - C^2}} \right],$$  

(44)

where $\gamma$ is the auxiliary parameter given by

$$\gamma = \frac{\rho M + \rho H - 2\rho C}{HM - C^2}. \quad (45)$$

This expression for the squared ‘slowness’ is similar to that given by Pride (2005) for a plane wave in a homogeneous medium. However, eq. (44) is valid for a medium with smoothly varying heterogeneity of arbitrary magnitude. Factoring $\gamma$ out from under the radical I can write eq. (44) as

$$p^2 = \frac{\gamma \omega^2}{2} \left[ 1 \pm \sqrt{1 - \frac{4(\rho \hat{\rho} - \rho C^2)}{\gamma^2 HM - C^2}} \right],$$  

(46)

or

$$p^2 = \frac{\gamma \omega^2}{2} \left[ 1 \pm \sqrt{1 - \xi} \right],$$  

(47)

where

$$\xi = \frac{4(\rho \hat{\rho} - \rho C^2)(HM - C^2)}{(\hat{\rho} H + \rho M - 2\rho C)^2}. \quad (48)$$

Expression (46) for the slowness provides a means for tracing rays and calculating the propagation path for a transient disturbance (Aki & Richards 1980; Kravtsov & Orlov 1990). Making use of the definition of $p$ I can write eq. (47) as a differential equation for $\theta(x, \omega)$

$$\nabla \theta \cdot \nabla \theta = \frac{\gamma \omega^2}{2} \left[ 1 \pm \sqrt{1 - \xi} \right],$$  

(49)

an eikonal equation for the longitudinal mode of displacement in a poroelastic medium. This scalar partial differential equation is equivalent to a system of ordinary differential equations for a trajectory $X(r)$ and the vector $p(r)$ (Courant & Hilbert 1962)

$$\frac{dX}{dr} = \frac{p}{\chi}, \quad (50)$$

$$\frac{dp}{dr} = \nabla \chi, \quad (51)$$

where $\chi(X, \omega)$ is the slowness, defined as

$$\chi(X, \omega) = \omega \sqrt{\frac{2}{\gamma} \left[ 1 \pm \sqrt{1 - \xi} \right]} \quad (52)$$

and $r$ is the distance along the trajectory $X(r)$. One can integrate the system of equations using a numerical technique such as a shooting method coupled to a globally convergent Newton–Raphson algorithm (Press et al. 1992). In addition, one may derive an integral expression for the phase $\theta(r, \omega)$ by writing the eikonal eq. (49) in ray coordinates, taking the square root and integrating

$$\theta(r, \omega) = \int_{X_0}^{X(r)} \chi(X(r'))dr' \quad (53)$$

or, more compactly,

$$\theta(r, \omega) = \omega \tau(r), \quad (54)$$

where

$$\tau(r) = \int_{X_0}^{X(r)} \sqrt{\frac{2}{\gamma} \left[ 1 \pm \sqrt{1 - \xi} \right]} dr'. \quad (55)$$

The coupled differential eqs (50) and (51) are used to construct trajectories or rays between a source and an observation point. The trajectories form the basis for efficient forward modelling of poroelastic propagation. Furthermore, they allow for semi-analytic expressions for model parameter sensitivities and the solution of the inverse problem (Menke 1984). For example, the rays form the basis for traveltime tomographic imaging which has proven highly successful in seismology (Nolet 1987; Iyer & Hirahara 1993) among other fields. Note that, in the most general setting the slowness can be complex and one must resort to complex ray tracing (Kravtsov et al. 1999; Amodei et al. 2006). Complex eikonal appears when the propagation behaviour can vary from hyperbolic wave propagation to diffusive decay, as in broad-band electromagnetic modelling (Vasco 2007).

An alternative to ray tracing involves solving the eikonal equation, the non-linear partial differential eq. (49), numerically. This approach is now well established and has been applied to a number of practical problems and seems quite stable (Setnian 1999). It was introduced to seismology by Vidale (1988) and has been generalized in various ways. Note that, to date, the method has not yet been extended to complex eikonal equations. Thus, currently, it can only be applied to certain regimes of poroelastic propagation.

**Transverse displacements**

Following a similar procedure, I consider the potential eigenvector $e^\perp$, given by eq. (36), and the resulting equation

$$\Gamma e^\perp = \lambda^\perp e^\perp, \quad (56)$$

where $\Gamma$ is the coefficient matrix in (34) and $\lambda^\perp$ is a scalar to be determined. Taking into account the coefficient matrix (34) and carrying out the matrix–vector multiplications by $p^\perp$ I arrive at the following linear system of equations

$$\begin{bmatrix} \alpha y_1 + \omega^2 \rho_1 y_2 \\ \omega^2 \rho_1 y_2 \end{bmatrix} = \lambda^\perp \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} \quad (57)$$

$$\begin{bmatrix} \alpha y_1 + \omega^2 \rho_1 y_2 \\ \omega^2 \rho_1 y_2 \end{bmatrix} = \lambda^\perp \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} \quad (58)$$

which may be written as a matrix equation for $y_1$ and $y_2$,

$$\begin{bmatrix} \alpha - \lambda^\perp & \omega^2 \rho_1 \\ \omega^2 \rho_1 & \omega^2 \rho_1 - \lambda^\perp \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}. \quad (59)$$

The linear system of equations has a non-trivial solution if

$$\text{det} \begin{bmatrix} \alpha - \lambda^\perp & \omega^2 \rho_1 \\ \omega^2 \rho_1 & \omega^2 \rho_1 - \lambda^\perp \end{bmatrix} = 0$$

(60)

which, after noting that $\alpha = \omega^2 \rho - Gp^2$, and setting $\lambda^\perp$ equal to zero, produces a quadratic equation for $p$

$$\omega^2 \rho (\omega^2 \rho - Gp^2) = (\omega^2 \rho_1)^2. \quad (61)$$

Thus, I have produced an equation for $p$

$$p^2 = \omega^2 \left[ \rho - \left( \frac{\omega^2}{\rho} \right) \rho_1 \right] \quad (62)$$

which leads to the eikonal equation for transverse displacements in a poroelastic medium

$$\nabla \theta \cdot \nabla \theta = \omega^2 \left[ \rho - \left( \frac{\omega^2}{\rho} \right) \rho_1 \right] \quad (63)$$
a simple modification of the eikonal equation for an elastic medium
\[ \nabla \theta \cdot \nabla \theta = \omega^2 \frac{\rho}{G} \]  
(64).

(Aki & Richards 1980). As for the longitudinal displacements, I can define a slowness, \( \chi(X, \omega) \), for the transverse motion,
\[ \chi(X, \omega) = \omega \sqrt{\frac{\rho - \frac{\omega^2}{\omega_c^2} \rho_c}{G}}. \]  
(65).

As expected, the transverse displacement depends upon the moduli \( \rho \) and \( G \). In addition, the transverse displacement also depends upon the properties of the fluid and the permeability through the presence of \( \rho_c \) and \( \tilde{p} \) in (62).

Note that, while the longitudinal component is uniquely determined as the normal to the surface of constant phase, via its definition (29), the transverse component can lie within the 2-D plane tangent to this surface. Thus, there is some degree of freedom for the transverse component to change orientation. Partitioning the transverse mode of propagation into components leads to the study of the vertical and horizontal shear waves.

2.2.2 Terms of order \( \varepsilon \): an expression for the amplitude

Next, I consider terms of order \( \varepsilon \), which gives two sets of equations containing phase and amplitude terms. My starting point is the set of eqs (A16) and (A17) in Appendix A. As noted in the previous subsection, there are two modes of propagation: longitudinal motion and transverse motion, each with a distinct propagation speed. To make progress I need to consider the longitudinal and transverse modes of propagation in greater detail.

**Longitudinal displacements**

For longitudinal displacements \( U \) is a vector in the same direction as \( \mathbf{p} \). For simplicity, I assume that all the contributions in the series (18) and (19) are proportional to \( \mathbf{p} \). Further, assume that \( U_1 \) and \( W_1 \) are vectors which satisfy eq. (34). Thus, the terms containing \( U_1 \) and \( W_1 \) cancel and I obtain two sets of equations for \( U_0 \) and \( W_0 \), given that the phase \( \theta \) is found by solving the eikonal eq. (49),
\[ 2p(\mathbf{p} \cdot \nabla G) U_0 - \frac{2}{3} \nabla G \rho^2 U_0 + \nabla K \rho^2 U_0 + \nabla C p^2 W_0 \]
\[ + G [(\nabla \cdot \mathbf{p}) p U_0 + 2p \cdot (\nabla (p U_0))] \]
\[ + G \left[ (\nabla \cdot (p U_0) \mathbf{p} + U_0 p \cdot \nabla \mathbf{p} + \mathbf{p} \cdot (\nabla (p U_0))^T \right] \]
\[ - \frac{2}{3} G \left[ \nabla (p^2 U_0) + p \nabla \cdot (p U_0) \right] \]
\[ + K_s \left[ \nabla (p^2 U_0) + p \nabla \cdot (p U_0) \right] \]
\[ + C \left[ \nabla (p^2 W_0) + p \nabla \cdot (p W_0) \right] = 0 \]  
(66).

And
\[ \nabla C p^2 U_0 + \nabla M (p^2 W_0) \]
\[ + C \left[ \nabla (p^2 U_0) + p \nabla \cdot (p U_0) \right] \]
\[ + M \left[ \nabla (p^2 W_0) + p \nabla \cdot (p W_0) \right] = 0. \]  
(67).

Note that eqs (66) and (67) comprise six equations for the two unknowns \( U_0 \) and \( W_0 \). The system can be reduced to two equations for two unknowns by projecting onto the vector \( \mathbf{p} \), a unit vector in the direction of the vector \( \mathbf{p} \). After projecting onto \( \mathbf{p} \), expanding the dyadic and differential operators, and grouping like terms, I arrive at the equations
\[ 2p H \mathbf{p} \cdot \nabla U_0 + (H \nabla \cdot \mathbf{p} + 2H \mathbf{p} \cdot \nabla p + p \mathbf{p} \cdot \nabla H) U_0 \]
\[ + 2p C \mathbf{p} \cdot \nabla W_0 + (C \nabla \cdot \mathbf{p} + 2C \mathbf{p} \cdot \nabla p + p \mathbf{p} \cdot \nabla C) W_0 = 0 \]  
(68).

And
\[ 2p C \mathbf{p} \cdot \nabla U_0 + (C \nabla \cdot \mathbf{p} + 2C \mathbf{p} \cdot \nabla p + p \mathbf{p} \cdot \nabla C) U_0 \]
\[ + 2p M \mathbf{p} \cdot \nabla W_0 + (M \nabla \cdot \mathbf{p} + 2M \mathbf{p} \cdot \nabla p + p \mathbf{p} \cdot \nabla M) W_0, \]  
(69)

where as defined in (43), \( H = K_a + 4/3G \). Because the gradients of \( U_0 \) and \( W_0 \) are projected onto the trajectory \( X(r) \) in eqs (68) and (69), they represent the changes along the ray path. Thus, I may consider eqs (68) and (69) to be a system of differential equations for \( U_0 \) and \( W_0 \) and write all projected gradients as derivatives with respect to \( r \) the position along the trajectory \( X(r) \). Also, because of the eikonal eq. (47) or (49), I can replace \( p \) by the slowness \( \chi(X, \omega) \), as defined in eq. (52). I can write these equations more compactly if I define the coefficients
\[ \Upsilon_{11} = 2 \chi H, \]  
(70)
\[ \Upsilon_{12} = 2 \chi C, \]  
(71)
\[ \Upsilon_{12} = 2 \chi C, \]  
(72)
\[ \Upsilon_{21} = 2 \chi C, \]  
(73)
\[ \Upsilon_{21} = 2 \chi C, \]  
(74)
\[ \Upsilon_{21} = 2 \chi C, \]  
(75)
\[ \Upsilon_{22} = 2 \chi M, \]  
(76)
\[ \Upsilon_{22} = 2 \chi M, \]  
(77)

Then, eqs (68) and (69) can be written as
\[ \Upsilon \frac{dV}{dr} + \Omega V = 0, \]  
(78)

where
\[ \mathbf{V} = \begin{pmatrix} U_0 \\ W_0 \end{pmatrix}, \]  
(79)

and \( \Upsilon \) and \( \Omega \) are matrices with the coefficients given above. Note, both the matrices \( \Upsilon \) and \( \Omega \) are symmetric and the matrix \( \Upsilon \)
\[ \Upsilon = 2 \chi \begin{pmatrix} H & C \\ C & M \end{pmatrix}, \]  
(80)

has the explicit inverse
\[ \Upsilon^{-1} = \frac{1}{2 \chi \left( HM - C^2 \right)} \begin{pmatrix} M & -C \\ -C & H \end{pmatrix}, \]  
(81)

which is defined as long as \( \chi \) and \( HM - C^2 \) do not vanish. Multiplying the terms of eq. (78) by \( \Upsilon^{-1} \) results in the equation
\[ \frac{dV}{dr} = -\Gamma V, \]  
(82)

GJI, 179, 299–318
Journal compilation © 2009 RAS
No claim to original US government works
where
\[ \Gamma = Y^{-1} \Omega. \]

Note that for a homogeneous medium
\[ \Gamma = Y^{-1} \Omega = \frac{\nabla \cdot p}{2\chi} Y^{-1} Y = \frac{\nabla \cdot p}{2\chi} I \]
and eq. (82) decouples to produce two equations which may be solved exactly for \( U_0 \) and \( W_0 \)
\[ U_0(X, \omega) = A_0^u \exp \left[ - \int_{X(0)}^{X(r)} \frac{\nabla \cdot p}{2\chi} dr \right] \]
\[ W_0(X, \omega) = A_0^w \exp \left[ - \int_{X(0)}^{X(r)} \frac{\nabla \cdot p}{2\chi} dr \right], \]
where \( A_0^u \) and \( A_0^w \) are the initial amplitudes of the solid and relative fluid displacements and \( X(r) \) denotes the trajectory which provides the path of integration. This is simply the amplitude decay due to the geometrical spreading of the wavefield as it propagates away from the source (Kline & Kay 1979; Kravtsov & Orlov 1990).

For a heterogeneous medium the first-order system of eqs (82) can be solved in its present form using a numerical technique or, as shown in Appendix B, the system can be written as two uncoupled, second-order differential equations for \( U_0 \) and \( W_0 \). The governing equation for the amplitude of the solid displacement vector is given by
\[ \frac{d^2 U_0}{dr^2} + \Psi_1 \frac{dU_0}{dr} + \Psi_2 U_0 = 0, \]
a linear, second-order differential equation for \( U_0 \) with variable coefficients given in terms of the elements of the matrix \( \Gamma \)
\[ \Psi_1(r) = \Gamma_{12} \frac{d}{dr} \left( \frac{1}{\Gamma_{12}} \right) + \Gamma_{11} + \Gamma_{22}. \]
\[ \Psi_2(r) = \Gamma_{12} \frac{d}{dr} \left( \frac{\Gamma_{11}}{\Gamma_{12}} \right) - \Gamma_{12} \Gamma_{21} + \Gamma_{11} \Gamma_{22}. \]

Similarly, I can derive a governing equation for \( W_0 \)
\[ \frac{d^2 W_0}{dr^2} + \Phi_1 \frac{dW_0}{dr} + \Phi_2 W_0 = 0, \]
where
\[ \Phi_1(r) = \Gamma_{21} \frac{d}{dr} \left( \frac{1}{\Gamma_{21}} \right) + \Gamma_{11} + \Gamma_{22}. \]
\[ \Phi_2(r) = \Gamma_{21} \frac{d}{dr} \left( \frac{\Gamma_{22}}{\Gamma_{21}} \right) - \Gamma_{12} \Gamma_{21} + \Gamma_{11} \Gamma_{22}. \]

Such decoupling in the frequency domain was noted by (Berryman 1983). These two scalar, ordinary differential equations may be solved efficiently using widely available numerical techniques (Press et al. 1992). Alternatively, an asymptotic technique may be used to derive semi-analytic solutions (Keller & Lewis 1995).

Transverse displacements

For transverse displacements \( U \) is a vector lying in the plane perpendicular to \( p \), which I shall denote by \( p^\perp \). As noted earlier, there is some freedom in the orientation of \( p^\perp \) as it may lie within a 2-D plane. Under the same assumptions invoked for the longitudinal displacements, I consider the terms of order \( \varepsilon^4 \), as given in eqs (A16) and (A17) for the case in which \( U_0, U_1, W_0 \) and \( W_1 \) are oriented in the direction \( p^\perp \). The resulting equations are
\[ p (\nabla G \cdot p^\perp) U_0 + p^\perp (\nabla G \cdot p) U_0 \]
\[ + G \left[ p^\perp (\nabla \cdot p) U_0 + 2p \cdot \nabla (U_0 p^\perp) \right] \]
\[ + G \left[ p \cdot p^\perp - (U_0 p^\perp) + p \cdot \nabla (U_0 p^\perp) \right] \]
\[ - \frac{2}{3} \left[ p \cdot p^\perp \right] \]
\[ + \Gamma_{21} \frac{d}{dr} \left( \frac{\Gamma_{22}}{\Gamma_{21}} \right) - \Gamma_{12} \Gamma_{21} + \Gamma_{11} \Gamma_{22}. \]
2.3 The nature of the longitudinal Biot slow and fast waves in the limit of low frequency

It is difficult to make definitive statements regarding the nature of the two solutions in eq. (47) due to the coupling of the fluid flow and the elastic deformation in the matrix. However, if I consider a low-frequency solution it is possible to make further progress. I should point out that in considering lower frequencies the scale length of the disturbance will lengthen. Hence, I am limiting the solution to a medium with heterogeneity of a sufficiently long scale length. At lower frequencies the Biot equations decouple, as noted by Pride (2005) and Lo et al. (2006), and the numerator and denominator of $\zeta$ are dominated by $\tilde{\rho}$ [see eq. (48)]. As indicated by the definition (26), if $K$ is not a function of frequency then $\tilde{\rho}$ is proportional to $1/\omega$, becoming large as $\omega$ approaches zero. Thus, as $\omega$ approaches zero $\zeta$ approaches

$$\zeta = -i \frac{4\rho(HM - C^2)K}{\eta H^2} \omega.$$  

When $K$ is a function of frequency $\omega$, the behaviour of $\zeta$ depends upon the relationship of $K$ to the frequency. For low frequencies, $\zeta$ smaller than 1, I can use the binomial expansion to write the square root term in eq. (47) as a power series in $\zeta$. Retaining only the first two terms of the expansion I obtain

$$p^2 = \frac{\gamma \omega^2}{2} \left[ 1 \pm \left( 1 - \frac{1}{2} \zeta \right) \right].$$  

(104)

The magnitude of the phase gradient vector $p$ is related to the inverse of the frequency of the propagating disturbance (Aki & Richards 1980), so that larger values of $\tilde{\rho}$ correspond to slower moving features. Because $\zeta$ is taken to be smaller than 1 the first root

$$p^2 = \frac{\gamma \omega^2}{2} \left( 2 - \frac{1}{2} \tilde{\rho}^2 \right)$$  

(105)

is known as the ‘Biot slow wave’, corresponding to a propagating, diffusive wave, related to a fluid pressure transient (Vasco et al. 2000; Vasco 2008a). The second root results in an expression for the ‘Biot fast wave’

$$p^2 = \frac{\gamma \zeta \omega^2}{4}$$  

(106)

which is the porous medium equivalent of an elastic wave and propagates with much less attenuation and a much higher velocity (Pride 2005). Accounting for the exact expressions for $\gamma$, eq. (45) and $\zeta$, eq. (48), I can write the eq. (106) for the fast wave as

$$p^2 = \omega^2 \frac{\rho \tilde{\rho} - \rho_1^2}{\tilde{\rho} H + \rho M - 2 \rho_1 C}$$  

(107)

or as

$$p^2 = \omega^2 \frac{\rho - \rho_1 \rho_1}{\tilde{\rho} H + \rho_1 M - 2 \rho_1 C}.$$  

(108)

Comparing the expression for a porous medium (108) to that for a purely elastic medium

$$p^2 = \omega^2 \frac{\rho}{H},$$  

(109)

the modifications required to account for poroelastic processes are apparent. Note that, while the frequency dependence of an elastic disturbance (109) is straightforward and represents hyperbolic wave propagation, the frequency dependence of a disturbance in a poroelastic medium (108) is rather more complicated due to the presence of the parameter $\tilde{\rho}$, which is defined in (26). This is particularly true if $K$ is also a function of frequency, leading to more complex propagation, including dispersion and dissipation. In the next two subsections I consider these two modes of longitudinal displacement in somewhat more detail. Specifically, I derive the form of the zeroth-order asymptotic solutions $U_0$ and $W_0$ in both the frequency and time domains in the limit of low frequency. As noted by (Pride 2005), the boundary of the low frequency regime lies in the kilo-Hertz to mega-Hertz range and covers the vast majority of seismic and hydrologic field experiments.

2.3.1 The Biot slow wave

First, consider the Biot slow wave whose slowness is given by eq. (105), which may written as

$$p^2 = \frac{\gamma \omega^2 - \frac{\gamma \zeta \omega^2}{4}}{4}$$  

(110)

in the low frequency limit. In the limit as $\omega$ approaches zero I find that

$$\lim_{\omega \to 0} \gamma = \frac{\tilde{\rho} H}{HM - C^2} = \frac{i \eta}{\omega K (HM - C^2)}$$  

(111)

and

$$\lim_{\omega \to 0} \zeta = 4 \frac{\rho K (HM - C^2)}{\eta H^2}$$  

(112)

and eq. (110) takes the form

$$p^2 = \frac{\gamma \omega^2}{4 K (HM - C^2)}.$$  

(113)

which, for $\omega$ near zero, is dominated by the first term on the right-hand side

$$p^2 = \frac{\gamma \omega^2}{4 K (HM - C^2)}.$$  

(114)

Drawing upon eq. (114) I can write the low frequency approximation to the eikonal equation for the Biot slow wave as

$$\nabla \theta \cdot \nabla \theta = \frac{i \omega}{K(HM - C^2)}.$$  

(115)

As stated previously in the discussion associated with eqs (49) through (55), I can define the slowness as the square root of the right-hand side of eq. (115),

$$\chi(X, \omega) = \frac{\omega}{K(HM - C^2)}.$$  

(116)

Expressing the eikonal equation in ray coordinates, along the trajectory $X(r)$ I arrive at an integral expression for the phase $\theta(r, \omega)$

$$\theta(r, \omega) = \int_{X_0} \chi(X(r'))dr'$$  

(117)

or, moving $i\omega$ outside the integral and defining

$$\tau(r) = \int_{X_0} \sqrt{\frac{\eta}{K(HM - C^2)}}dr',$$  

(118)

the phase may be written in the form

$$\theta(r, \omega) = \sqrt{\omega \tau(r)}.$$  

(119)
Now consider the zeroth-order term in the power series representation of $U(X, \omega, \theta)$ and $W(X, \omega, \theta)$ [eqs (18) and (19)]

$$U(X, \omega, \theta) = e^{\theta} U_0(X, \omega)$$

$$W(X, \omega, \theta) = e^{\theta} W_0(X, \omega)$$

which provides a suitable approximation to the solid and fluid displacements if $\varepsilon$ is small. Substituting the expression for the phase, $\theta(r, \omega)$, and the fact that $u_0 = U_0 p$ and $W_0 = W_0 p$ the above expressions take the form

$$U(X, \omega, \theta) = e^{\sqrt{-\omega} \tau(X)} U_0(X, \omega)p$$

$$W(X, \omega, \theta) = e^{\sqrt{-\omega} \tau(X)} W_0(X, \omega)p$$

where $X(r)$ a point on the trajectory a distance $r$ from the source of the disturbance. Inverse Fourier transforming eqs (122) and (123) back into the time domain, using the fact that the inverse Fourier transform of a product is the convolution of the inverse Fourier transforms and the inverse transform of $e^{\sqrt{-\omega}}$ is a Gaussian (Spiegel 1990; Virieux et al. 1994).

$$u(X, t, \theta) = \frac{\tau}{2\sqrt{\pi}t^3} e^{-\tau^2/4t} H(t) * u_0(X, t)p$$

$$w(X, t, \theta) = \frac{\tau}{2\sqrt{\pi}t^3} e^{-\tau^2/4t} H(t) * w_0(X, t)p.$$  

where $*$ signifies a temporal convolution and $u_0(X, t)$, $w_0(X, t)$ are the inverse transforms of $U_0(X, \omega)$ and $W_0(X, \omega)$, and $H(t)$ is the Heaviside or step-function which jumps in value from zero to one at $t = 0$.

The phase behaviour in (124) and (125) contains a Gaussian impulse response which is the solution to the diffusion equation (Carslaw & Jaeger 1959). This form of the solution agrees with previous studies in homogeneous media where it was found that the low frequency Biot slow wave satisfies a diffusion-type equation (see Pride 2005; Lo et al. 2006). Such a solution is also in agreement with solutions for quasi-static pressure and displacement in a poroelastic medium (Rudnicki 1986; Wang & Kumpel 2000; Vasco 2008a). The solutions (124) and (125) decay rapidly with propagation distance and do not behave like elastic waves. However, it is still possible to consider the propagating transient disturbance as a type of wave and to define an ‘arrival time’ and to use such arrival times to perform something akin to traveltime tomography (Virieux et al. 1994; Vasco et al. 2000; Shapiro et al. 2002; Vasco et al. 2008). In order to gain some insight, consider the solution in the time domain, eq. (124), when the amplitude function $u_0(X, t)$ does not depend upon time. The peak of the displacement occurs when the temporal derivative vanishes, that is when

$$\frac{\partial u(X, t, \theta)}{\partial t} = \frac{\tau}{2\sqrt{\pi}t^3} e^{-\tau^2/4t} \left[ -\frac{3}{2\sqrt{\pi}t^5} + \frac{\tau}{4\sqrt{\pi}t^7} \right] u_0(X)p$$

is equal to zero. This condition is satisfied when the quantity inside the square brackets vanishes, that is when

$$t = \frac{\tau^2}{6}$$  

or

$$\tau = \frac{\sqrt{6} T_{peak}}{\sqrt{\pi}}$$  

where $T_{peak}$ is the time at which the displacement attains a maximum value. Thus the ‘phase’, $\tau(X)$ is proportional to the square root of the time at which the peak deformation occurs. One can use this quantity to define an ‘arrival time’ for the diffusive transient displacement (Virieux et al. 1994). For more a complicated source–time function $u_0(X, t)$ it is necessary to remove it from the recorded displacement before computing the arrival time. If the source–time function is known, it may be removed by deconvolution in the time or frequency domain (Bracewell 1978).

The expressions for the matrix and fluid displacements (124) and (125) correspond to a delta function source in time. That is, to an impulsive source in which the displacement is non-zero at a single point in time. Due to the diffusive nature of the propagation of the Biot slow wave such an initial pulse will not propagate very far from the source. Rather, it is more common to have a step function source in which fluid is introduced at a point for a long period of time. That is, initially the flow rate is zero and then steps up to some non-zero value very quickly and is maintained at that rate for a long period of time. In that way the constant flux of mass or energy propagates some distance from the source. I can obtain this type of source by integrating the delta function in time. The integral of a delta function is a step function (Bracewell 1978), and the integral of the impulse response is given by

$$u(X, t, \theta) = \int_0^t \frac{\tau}{2\sqrt{\pi}p^3} e^{-\tau^2/4p^2} H(t) * u_0(X, t)p$$

$$w(X, t, \theta) = \int_0^t \frac{\tau}{2\sqrt{\pi}p^3} e^{-\tau^2/4p^2} H(t) * w_0(X, t)p.$$  

The integral is related to the complementary error function (Press et al. 1992) and so I can write eqs (129) and (130) as

$$u(X, t, \theta) = \text{erfc} \left( \frac{\tau}{2\sqrt{\pi}p^2} \right) * u_0(X, t)p$$

$$w(X, t, \theta) = \text{erfc} \left( \frac{\tau}{2\sqrt{\pi}p^2} \right) * w_0(X, t)p$$

which is similar to the solution for fluid diffusion due to constant fluid injection of withdrawal (Theis 1935).

### 2.3.2 The Biot fast wave

Now I consider the second possible value for $p^2$ in eq. (104), associated with the minus sign, which results in

$$p^2 = \frac{\gamma \rho^2}{4}$$

or, considering the limits of eqs (111) and (112),

$$p^2 = \omega^2 \frac{\rho}{H}$$

which is identical to the slowness for an elastic medium [eq. (109)]. The associated eikonal equation, obtained by substituting $\nabla \theta$ for $\nabla \psi$ [see the definition of $p$, eq. (29)], is

$$\nabla \theta \cdot \nabla \psi = \frac{\rho^2}{H}$$

As was done previously for the Biot slow wave, I can define the slowness

$$\chi(X, \omega) = \omega \sqrt{\frac{\rho^2}{H}}$$

Consideration of the eikonal equation in ray coordinates allows one to write the phase as the integral

$$\theta(r, \omega) = \omega \int_{x_0}^{x} \sqrt{\frac{\rho}{H}} d\gamma.$$
or as
\[ \theta(r, \omega) = \omega \tau(r), \]  
(138)
where
\[ \tau(r) = \int_{x_0} \sqrt{\frac{\rho}{H}} \, dr'. \]  
(139)

Now consider the zeroth-order approximation to the solid and fluid displacements given by
\[ U(X, \omega, \theta) = e^{i\omega t_0} U_0(X, \omega) \]  
(140)
\[ W(X, \omega, \theta) = e^{i\omega t_0} W_0(X, \omega). \]  
(141)
Substituting in the expression (138) for the phase \( \theta \) and accounting for the fact that \( U_0 \) and \( W_0 \) are longitudinal displacements (in the \( p \) direction), I arrive at the frequency domain representation
\[ U(X, \omega, \theta) = e^{i\omega t_0} U_0(X, \omega) \]  
(142)
\[ W(X, \omega, \theta) = e^{i\omega t_0} W_0(X, \omega) \]  
(143)
Applying the inverse Fourier transform to eqs (142) and (143) produces the time domain expressions
\[ u(X, t) = \delta(t - \tau) * u_0(X, t) \]  
(144)
\[ w(X, t) = \delta(t - \tau) * w_0(X, t) \]  
(145)
where \( \delta(t) \) is the delta function. The convolution with the delta function may be evaluated exactly (Bracewell 1978), resulting in
\[ u(X, t) = u_0(X, t - \tau) \]  
(146)
\[ w(X, t) = w_0(X, t - \tau). \]  
(147)
Thus, the waveforms are just shifted versions of the source waveform combined with changes due to propagation described by the amplitude eqs (87) and (90). This is in keeping with previous studies which indicate that the Biot fast wave is in essence an elastic wave propagating in the poroelastic medium (Pride 2005; Lo et al. 2006).

2.4 Nature of the transverse displacement in the limit of low frequency

The squared slowness associated with the transverse displacement is given by eq. (62)
\[ p^2 = \frac{\omega^2}{G} \left[ \rho - \frac{\omega}{G} \frac{\rho_i}{\eta} \right]. \]  
(148)
In order to obtain the exact dependence on the flow properties \( \eta \) and \( K \) and frequency \( \omega \), I substitute the expression for \( \rho \), eq. (26)
\[ p^2 = \frac{\omega^2 \rho}{G} + \frac{\omega^2 K(\rho)^2}{G \eta} \]  
(149)
which for low frequency, is dominated by the first term on the right-hand side. Thus, at low frequencies
\[ p^2 \approx \frac{\omega^2 \rho}{G} \]  
(150)
and
\[ \chi(X, \omega) = \omega \sqrt{\frac{\rho}{G}}. \]  
(151)
Consideration of the eikonal equation in ray coordinates enables me to write the phase as
\[ \theta(r, \omega) = \omega \tau(r), \]  
(152)
where
\[ \tau(r) = \int_{x_0} \sqrt{\frac{\rho}{G}} \, dr'. \]  
(153)
The zeroth-order approximation to the solid displacement is given by
\[ U(X, \omega, \theta) = e^{i\omega t_0} U_0(X, \omega) \]  
(154)
Applying the inverse Fourier transform to eqs (154) produces the time domain expression
\[ u(X, t) = \delta(t - \tau) * u_0(X, t) \]  
(155)
where \( \delta(t) \) is the delta function. The convolution with the delta function may be evaluated exactly (Bracewell 1978), resulting in
\[ u(X, t) = u_0(X, t - \tau) \]  
(156)
where \( \tau \) is the time delay corresponding to the transverse displacement, eq. (153).

2.5 Propagation across an Interface

As with ray theoretical approaches for modeling elastic wave propagation, one can include a discontinuous change in material properties as a boundary and subject the wavefields to the appropriate boundary conditions (Aki & Richards 1980; Chapman 2004). Hence, one can use the asymptotic expressions given above in models containing layering, faults, and other structural and stratigraphic features. Due to the presence of the Biot slow wave and the fluid displacement field, the interaction of the wavefield with an interface in a poroelastic medium will be a somewhat richer topic, with four possible reflected and transmitted waves [fast longitudinal, fast in-plane transverse (SV), fast out-of-plane transverse (SH), and slow longitudinal] for each incident wave. The longitudinal mode of propagation will have two associated displacement fields, one associated with the solid displacement \( U \) and the other associated with the relative fluid displacement \( W \). The transverse mode of propagation will only include solid displacements, as indicated by the equation governing the amplitude (95). A discussion of reflection and transmission coefficients warrants an entire paper, and will be the subject of future work. Such a treatment involves a direct extension of the results for an elastic medium (Aki & Richards 1980; Chapman 2004).

2.6 Computation of the complete displacement response

Given that there are two modes of longitudinal propagation, the Biot slow and fast waves, with very different propagation characteristics, some thought must be given to the computation of the complete response at a given point. In particular, the fact that the Biot fast waves decays slowly, essentially as an elastic wave, means that a particular station may receive contributions from many different locations. Stated another way, a large pressure change can generate a continuous contribution of Biot fast waves as it propagates (Vasco 2008a). Because the Biot fast waves can travel significant distances without much decay, one must account for these contributions in computing the displacement response at a given location.
Conversely, a Biot fast wave can generate a Biot slow wave near the receiver and contribute to the local pressure response. This process may be responsible to the dynamic triggering of microseismicity by large, remote earthquakes.

In this subsection, I will touch upon the summation of Biot fast wave contributions from a pressure source, as generated by the injection or withdrawal of fluid from a well. This is a particularly common situation, encountered in groundwater, geothermal, petroleum and waste disposal activities. I consider an impulsive pressure source, which will generate both Biot slow and fast waves. The Biot slow wave will propagate from the source point \( X \) to an intermediate location \( X \) and the disturbance is given by eq. (124),

\[
u(X, X; t) = \frac{\tau(X, X)}{2\sqrt{\pi t^3}} \exp\left[-\tau(X, X)^2/4t\right] \\
\times \Omega_0(X, X) p(X, t),
\]

where \( \Omega_0(X, X) \) represents the amplitude decay of the slow wave due to propagation from \( X \) to \( X \). Similarly, \( \tau(X, X) \) represents the accumulated phase change as the diffusive slow wave propagates from the source point \( X \). As the Biot slow wave propagates from the source location \( X \) to the intermediate point in the medium it will generate, or shed, Biot fast waves. Once the fast waves are generated, say at the point \( X \), they will propagate to the receiver point \( X \) according to eq. (146). I shall denote the accumulated phase due to the propagation of the Biot fast wave from \( X \) to the receiver point \( X \) by \( \tau(X, X) \) and similarly for the amplitude decay \( \Omega_0(X, X) \). One consideration in the generation of the longitudinal displacement for the Biot fast wave is that the trajectories of the outgoing fast wave may differ from that of the incoming Biot slow wave. Thus, I include a term accounting for the projection of the displacement associated with the Biot slow wave onto the displacement direction of the outgoing fast wave. The contribution to the displacement at the receiver located at \( X \) for a wave that travelled as a slow wave to from \( X \) to \( X \), and then as a fast wave from \( X \) to \( X \), is

\[
u(X, X; t) = \frac{\tau(X, X)}{2\sqrt{\pi t^3}} \exp\left[-\tau(X, X)^2/4t\right] \\
\times \Omega_0(X, X) \Omega_0(X, X) p(X, t) \cdot p(X, t) p(X, t),
\]

where \( \Omega_0(X, X) \) is obtained by summing or integrating over all intermediate points \( X \)

\[
u(X, X; t) = \int_X u_0(X, X; t) dX.
\]

One can evaluate this integral directly using numerical methods or approximate it using an asymptotic technique (Dingle 1973). The procedure is similar to the quasi-static calculation for the solid displacement due to a pressure source presented in Wang (2000, p. 110).

3 APPLICATIONS

In this section, I implement the methodology described above and use it to model fluid pressure changes and solid matrix displacements due to fluid injection into a borehole. Two particular cases are considered: homogeneous and heterogeneous media, and the results are compared with predictions from a finite difference code and an analytic solution for a homogeneous medium. I shall only be concerned with the computation of the direct longitudinal slow and fast arrivals. That is, I will not compute conversions between slow and fast arrivals, as indicated in eqs (158) and (159). An example of such a calculation, in the case of quasi-static poroelastic propagation, was given in Vasco (2008a).

3.1 Propagation in a homogeneous medium

Here, I am interested in modelling the evolution of fluid pressure and solid displacement in a homogeneous medium induced by a rapid pressure pulse (Fig. 1). The half-width of the pulse is less than 0.1 s and the pressure source is activated at 0.2 s. The medium is a homogeneous porous whole space with a solid bulk modulus of 30.5 GPa, an undrained bulk modulus of 20.5 GPa, a fluid bulk modulus of 2.2 GPa, a shear modulus of 8.4 GPa, a solid density of 2.5 gm cc^{-1}, a fluid density of 1.0 gm cc^{-1}, a porosity of 0.1, and a hydraulic conductivity of \( 3.0 \times 10^{-12} \). In order to reduce the computation I shall consider a two dimensional problem, modelling the propagation within a vertical slice of the Earth. A numerically stable finite difference code (Masson et al. 2006) is used to calculate the pressure and displacements due to the injection. In Fig. 2, three snap-shots of the pressure variation in the 2-D whole space are shown. Note that by 1000 s the pressure variation has reached the boundaries of the model and the predictions of the finite difference code will be influenced by this interaction.

For a homogeneous medium I can use the expression given in (Wang & Kumpel 2003) for the quasi-static pressure variation. The inertial terms are probably not significant in the governing equation for pressure if the frequency is low. This conjecture is verified through a comparison of pressure predictions made using the finite-difference approach of (Masson et al. 2006), the analytic predictions of (Wang & Kumpel 2003), and the asymptotic expression given by eq. (125) of this paper (Fig. 3). In general, the agreement between the three methods is fairly good though the agreement with the numerical results deteriorate somewhat after the peak pressure is obtained. The differences after the peak pressure may be due to the interaction of the pressure with the boundary in the numerical modelling (Fig. 2). The differences between the asymptotic pressure estimates and the analytic and the finite-difference estimates are shown in greater detail in Fig. 4 where I plot the absolute error.
Figure 2. Three snapshots from the finite-difference modelling of Biot's poroelastic equations. The snapshots display the pressure variation due to the source pulse, shown in Fig. 1, applied at the center of the simulation grid. The observation point, the location at which the time variation of pressure is calculated, is indicated by an open triangle.

Figure 3. A comparison of the numerical calculation of pressure (Numeric), an analytic solution for pressure (Analytic), and the asymptotic solution (Asymptotic) given by eq. (125). Each pressure curve has been normalized such that its peak value is unity.

Figure 4. The difference between the asymptotic solution and the numeric and analytic solutions. The error is given in terms of the percentage of the normalized peak value. Thus, in this case, the error never exceeds roughly 2 per cent of the peak value.

as a function of time. In general, the error is less then 2 per cent of the peak pressure value plotted in Fig. 3.

The inertial terms cannot be neglected when calculating the elastic displacement of the solid matrix. Doing so will give the correct elastic quasi-static response to the pressure changes near the injection point, that is the response modelled using eqs (158) and (159). However, the quasi-static solution does not contain the Biot fast wave which is generated by the rapid pressure change due to injection. For an analytic model of the Biot fast wave I use the expressions provided by (Gajo & Mongiovi 1995). In addition, I generate a numerical solution using the finite-difference code of (Masson et al. 2006). Three snap-shots, generated within the first 0.3 s after the start of injection, are shown in Fig. 5. Note the interaction of the Biot fast wave, which is essentially an elastic wave, with the boundaries.
Modelling broad-band poroelastic propagation

Figure 5. Three snapshots from the finite-difference modelling of Biot’s poroelastic equations. The snapshots show the radial displacement of the solid matrix due to the pressure pulse shown in Fig. 1.

Figure 6. A comparison of the numerical calculation of the radial displacement of the solid matrix, an analytic solution for the displacement, and the asymptotic solution given by eq. (146). Each curve has been normalized the peak value of displacement.

of the mesh by 0.28 s. The boundaries generate reflections, which impact the predictions made after that time. This points to some of the limitations of numerical approaches for modelling poroelastic processes. The timescale of the pressure variation (Fig. 2) is significantly different from that for the elastic wave (Fig. 5). Thus, the elastic wave traverses the entire numerical modelling grid by 300 iterations of the finite difference code. About 1000 000 iterations are necessary to model the propagation of the pressure disturbance from the source to the edge of the modelling grid, taking roughly 2 hr of CPU time. If I had doubled the size of the grid to avoid spurious reflections then the amount of computation increases by four times, requiring 8 hr of CPU times.

In Fig. 6, I compare the predictions of the numerical code with those of the analytic solution of (Gajo & Mongiovi 1995) and the asymptotic solution given for the Biot fast wave, eq. (146). When the phase term is real, the analytic and asymptotic solutions are shifted versions of the source function, after we account for the mapping of pressure into displacement which occurs at the source. The predictions of the three methods are fairly close until the displacement peak. Following the peak displacement, the numerical predictions deviate from the analytic and asymptotic predictions. As with the pressure, this may be due to the interaction of the finite-difference results with the boundary of the modelling grid. In addition, one must be careful when including the source–time function as noted by (Chapman 1985). For example, for an elastic wave one must consider the analytic time-series which contains both the source–time function as well as its Hilbert transform. The disagreement is shown in more detail in Fig. 7, where one finds exact agreement between the analytic and asymptotic displacements and increasing discrepancies between the numerical solution and the analytic and asymptotic solutions.

3.2 Propagation in a heterogeneous medium

In an effort to examine propagation in a heterogeneous medium I perturbed the uniform model given above, using linear and quadratic functions to generate a 2-D velocity model (Fig. 8). The resulting
Figure 7. The difference between the asymptotic solution and the numeric and analytic solutions. The differences are given in terms of their percentage of the peak value of the displacement curves, in this case 1.

Figure 8. The velocity variation of the Biot slow wave for the calculation of pressure and displacement in a heterogeneous medium. The model contains a high velocity layer bounded above and below by low velocity zones. The velocity of the layer also increases linearly to the right-hand side.

model constrains a high velocity zone bounded above and below by low velocity regions. The source is located at (0.5 km, 0.5 km), within the high velocity zone, while the receiver lies at the upper edge of the high velocity zone. From the results of the finite difference pressure calculations, one observes that the pressure propagation is very much influenced by the heterogeneities (Fig. 9). The rather asymmetric pressure distribution contrasts sharply with that of the homogeneous medium (Fig. 2). Solving the eikonal eq. (49) numerically using the fast marching method of (Sethian 1999), which was introduced in seismology by (Vidale 1988) one can compute the traveltime contours (Fig. 10). The trajectories for asymptotic modelling can be generated by marching down the gradient of the traveltime field (Sethian 1999). Such a trajectory connecting the source and receiver is shown in Fig. 10. The calculation of the phase field and the generation of the trajectory took around 5 CPU seconds on a workstation. In Fig. 11, I compare the numerical solution produced by the finite-difference code with the asymptotic solution given above. Note that the analytic solution is no longer valid, due to the presence of heterogeneity. Overall, there is relatively good agreement between the two predictions. The discrepancy between the two solutions is shown in more detail in Fig. 12. Generally, the two solutions lie within 2–4 per cent of each other.

In Fig. 13, I compare the displacement of the solid matrix associated with the Biot fast wave. As before, the solution was truncated due to interference from boundary reflections in the numerical modelling. There is general agreement between the two solutions and most of the differences occur after the peak of the pulse (Figure 14). As noted above, the numerical solution is influenced by the presence of the boundary in this time interval. The agreement between the asymptotic solution and the numerical predictions could be improved by expanding the modelling grid and accounting for the exact position of the source and receiver within the modelling grid. Furthermore, using the full frequency response, given in eq. (49), rather than the low frequency response (146), and the analytic source function (Chapman 1985), should improve the agreement.

4 CONCLUSIONS

An asymptotic approach provides a useful technique for modelling the propagation of a disturbance in a poroelastic medium with
Modelling broad-band poroelastic propagation

The variation of phase associated with the Biot slow wave, due to the heterogeneous velocity structure. The phase was calculated by numerically solving the eikonal equation for the velocity variation shown in Fig. 8 (Vidale 1988; Sethian 1999). The star denotes the location of the source and the open triangle denotes the location of the observation point. The trajectory which represents the propagation path of the slow wave is indicated by the solid curve.

A comparison of the numerical calculation of the radial displacement of the solid matrix and the asymptotic solution given by eq. (146). Each curve has been normalized the peak value of displacement.

Smoothly varying elastic and flow properties. Because the expansion is in terms of a scale parameter defined by the ratio of the width of the disturbance to the scale length of the heterogeneity, the solution should be valid across a range of frequencies as long as the heterogeneity is sufficiently smooth. The expressions for the phase and amplitudes of the longitudinal Biot fast and slow displacements and the transverse displacements are simple extensions of expressions for displacements in an elastic medium. In the limit of low frequency, the expressions capture the diffusive nature of the Biot slow wave and the hyperbolic wave-like nature of the longitudinal Biot fast wave and the transverse displacement. At higher frequencies the propagation can contain elements of diffusive and hyperbolic propagation and the slowness, as given in eq. (47), can be complex and require complex ray tracing (Kravtsov et al. 1999; Amodei et al. 2006; Vasco 2007). As noted above, it is possible to account for interfaces in the methodology, by treating a discontinuity as a boundary condition. An example of the refraction at a boundary for quasi-static propagation in a poroelastic medium was given in Vasco (2008a).

The trajectory-based solution derived in the paper provides additional insight into the manner in which the properties of the medium influence the propagation of disturbances within a poroelastic earth model. For example, the three modes of propagation, the fast and slow longitudinal displacements and the fast transverse...
displacement, are given by the three sets of eigenvalues and eigenvectors of the matrix (34). The three additional solutions required of the $6 \times 6$ matrix are provided by disturbances propagating in the reverse direction. The exact combination of the medium parameters and frequency contributing to the phase velocity of each mode of propagation follows from eqs (47) and (62). The variation of amplitude with propagation distance for each mode of propagation is given by the transport eqs (87) and (90) for the longitudinal displacements, and the expression (102) for the transverse displacement. These expressions are particularly useful when solving the inverse problem, in which observations are used to infer properties within the Earth (Iyer & Hirahara 1993). For example, the expressions allow the inverse problem to be partitioned into a traveltime inverse problem (Aki et al. 1976) and an amplitude inverse problem (Thomson 1983). The traveltime inverse problem is quasi-linear in nature and has better convergence properties to a solution than the amplitude inverse problem (Nolet 1987). It is also possible to formulate an efficient, low-order waveform inversion algorithm based upon the asymptotic solution (Vasco et al. 2003). The asymptotic formalism used here also unifies two classes of inverse problems: the inversion of displacement and seismic data (Vasco et al. 2003) and the inversion of fluid flow data (Vasco et al. 2000; Vasco 2008b).

There a number of avenues by which to extend this work. First, one could generalize the governing equations such that the moduli depend on the stress field and/or the fluid pressure. Second, one could consider multiphase fluid flow and the attendant complications. Third, more complicated rheologies, such as plasticity, could be invoked for the solid matrix. The method of multiple scales may be used for such generalizations because it is applicable to non-linear (Jeffrey & Kawahara 1982; Anile et al. 1993) and coupled (Korsunsky 1997) processes. There are also a number of possible applications of the methodology including the study of deformation accompanying reservoir production mentioned in Section 1. In addition, it would be of interest to explore the consequences of the conversion of longitudinal displacements between the Biot fast and slow waves. As noted by Pride (2005) and illustrated in Vasco (2008a), in a heterogeneous poroelastic medium, fast waves can generate slow waves and vice versa. Given the differences in the nature of propagation of these two modes, this leads to some interesting effects, such as the rapid appearance of elastic deformation as compared to the appearance the gradual appearance of pressure change (Vasco 2008a). Such conversions may be a factor in the remote triggering of micro-earthquakes by dynamic strains generated during a major earthquake (Hill et al. 1993).

**ACKNOWLEDGMENTS**

This work was supported by the Assistant Secretary, Office of Basic Energy Sciences of the U.S. Department of Energy under contract DE-AC03-76SF00098. I wish to thank S. Pride and Y. Masson for supplying the finite difference code for computing displacements in a poroelastic medium. All computations were carried out at the Center for Computational Seismology, Berkeley Laboratory.

**REFERENCES**

APPENDIX A: THE METHOD OF MULTIPLE SCALES

In this Appendix, I apply the method of multiple scales (Anile et al. 1993; Kevorkian & Cole 1996) to the equations governing the evolution of a transient disturbance in a poroelastic medium, eqs (15) and (16). These coupled linear partial differential equations depend on the spatially varying parameters $G(x)$, $K(x)$, $C(x)$, $M(x)$ and $X(x)$ as well as on the frequency $\omega$. One approach to solving this system of equations makes use of a series representation of the solution in powers of $1/\omega$ and assumes that $\omega$ is large. Because I am interested in modelling disturbances across a wide range of frequencies I shall not adopt this approach. Rather, I will assume that the heterogeneity is smoothly varying in comparison to scale of the disturbance in displacement and pressure. Specifically, if I denote the scale length of the heterogeneity by $L$ and the scale length over which the pressure and displacement varies by $l$. Then, by assumption, $L \gg l$ and the ratio $\varepsilon = l/L$ is much smaller then 1. In order to bring out the scale separation I can rewrite the governing equations in terms of a slow variable $X$ which is given by

$$\mathbf{X} = \varepsilon \mathbf{x}.$$  

(A1)

Furthermore, I can represent the Fourier transform of solid matrix displacement and the pore fluid displacement as power series in $\varepsilon$

$$\mathbf{U}(\mathbf{X}, \omega, \theta) = e^{i\omega \varepsilon} \sum_{l=0}^{\infty} \varepsilon^l \mathbf{U}_l(\mathbf{X}, \omega)$$  

(A2)

and

$$\mathbf{W}(\mathbf{X}, \omega, \theta) = e^{i\omega \varepsilon} \sum_{l=0}^{\infty} \varepsilon^l \mathbf{W}_l(\mathbf{X}, \omega).$$  

(A3)

Note that, because $\varepsilon \ll 1$, only the first few terms of the power series are significant. The form of the solutions (A2) and (A3) is a variation of the generalized plane wave expansion used in the study of elastic and electromagnetic waves (Luneburg 1966; Kline & Kay 1979; Aki & Richards 1980; Kravtsov & Orlov 1990) where $\theta(\mathbf{x}, \omega)$ is the phase of the disturbance, a quantity related to the propagation time. The phase is a rapidly varying quantity which scales as $1/\varepsilon$ (Anile et al. 1993). After Fourier transforming, the frequency only enters as part of the coefficients of the governing equations and I shall treat $\omega$ as a parameter. The differential operators in the governing equations may be written in terms of the slow variable $\mathbf{X}$ by noting that

$$\frac{\partial \mathbf{U}}{\partial x_i} = \varepsilon \frac{\partial \mathbf{U}}{\partial X_i} + \frac{\partial \theta}{\partial x_i} \frac{\partial \mathbf{U}}{\partial \theta}.$$  

(A4)

Hence, making use of eq. (A1) I can write the gradient operators as

$$\nabla \mathbf{U} = \varepsilon \nabla X \mathbf{U} + \nabla \theta \frac{\partial \mathbf{U}}{\partial \theta}.$$  

(A5)

$$\nabla \cdot \mathbf{U} = \varepsilon \nabla X \cdot \mathbf{U} + \nabla \theta \frac{\partial \mathbf{U}}{\partial \theta}.$$  

(A6)

where $\nabla X$ denotes the gradient with respect to the components of the slow variable $\mathbf{X}$. In the derivation that follows I shall suppress the $\mathbf{X}$ subscript on the differential operator $\nabla$.

The first step involves rewriting the governing equations in terms of the slow variables. Consider a version of the first eq. (15) in which I expand the derivative terms

$$\nabla G \cdot \nabla U + \nabla G \cdot (\nabla U)^T$$

$$- \frac{1}{2} \nabla G \cdot \left( [\nabla \cdot U] \right)$$

$$+ G \nabla \cdot \nabla U$$

$$+ G \nabla \cdot (\nabla U)^T$$

$$- \frac{1}{2} G \nabla \cdot \left( [\nabla \cdot U] \right)$$

$$+ \nabla K_s \nabla \cdot U$$

$$+ K_s \nabla \cdot (\nabla U)$$

$$+ \nabla C \nabla \cdot W$$

$$+ C \nabla \cdot (\nabla W)$$

$$+ \omega^2 \rho U + \omega^2 \rho_1 W = 0.$$  

(A7)
Now I substitute the differential operators as indicated in (A5) and (A6), only retaining terms containing $\varepsilon^0 \sim 1$ and $\varepsilon^1$,

\[
\varepsilon \nabla G \cdot \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) \\
+ \varepsilon \nabla G \cdot \left( \nabla \theta \frac{\partial U}{\partial \theta} \right)^T \\
- \frac{2}{3} \varepsilon \nabla G \cdot \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) I \\
+ \varepsilon \nabla G \cdot \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) + \varepsilon G \nabla \theta \cdot \nabla \left( \frac{\partial U}{\partial \theta} \right) + G \nabla \theta \cdot \left( \nabla \theta \frac{\partial^2 U}{\partial \theta^2} \right) \\
+ \varepsilon \nabla G \cdot \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) + \varepsilon G \nabla \theta \cdot \nabla \left( \frac{\partial U}{\partial \theta} \right) + G \nabla \theta \cdot \left( \nabla \theta \frac{\partial^2 U}{\partial \theta^2} \right)^T \\
- \frac{2}{3} \varepsilon \nabla G \cdot \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) I - \frac{2}{3} \varepsilon \nabla G \theta \cdot \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) I - \frac{2}{3} \varepsilon \nabla G \theta \\
\times \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) I \\
+ \varepsilon \nabla K_u \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) \\
+ \varepsilon K_u \nabla \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) + \varepsilon K_u \nabla \left( \nabla \theta \frac{\partial^2 U}{\partial \theta^2} \right) + K_u \nabla \theta \cdot \left( \nabla \theta \frac{\partial^2 U}{\partial \theta^2} \right) \\
+ \varepsilon \nabla C \left( \nabla \theta \frac{\partial W}{\partial \theta} \right) \\
+ \varepsilon C \nabla \theta \cdot \left( \nabla \theta \frac{\partial W}{\partial \theta} \right) + \varepsilon C \nabla \theta \cdot \left( \nabla \theta \frac{\partial^2 W}{\partial \theta^2} \right) + C \nabla \theta \cdot \left( \nabla \theta \frac{\partial^2 W}{\partial \theta^2} \right) \\
+ \omega^2 p \rho U + \omega^2 p \rho W = 0. \quad (A8)
\]

I can write eq. (A8) more compactly if I use the definition of $p = \nabla \theta$ and the fact that

\[
\frac{\partial U}{\partial \theta} = iU \\
\text{and}
\frac{\partial W}{\partial \theta} = iW
\]

which follows from the form of the solutions (A2) and (A3). Making these substitutions, I can write eq. (A8) as

\[
\varepsilon \nabla G \cdot (ipU) \\
+ \varepsilon \nabla G \cdot (ipU)^T \\
- \frac{2}{3} \varepsilon \nabla G \cdot [(ip \cdot U) I] \\
+ \varepsilon G \nabla \cdot (ipU) + \varepsilon G p \cdot \nabla (iU) - G p \cdot (pU) \\
+ \varepsilon G \nabla \cdot (ipU)^T + \varepsilon G p \cdot (\nabla U)^T - G p \cdot (pU)^T \\
- \frac{2}{3} \varepsilon \nabla G \cdot (ipU) I - \frac{2}{3} \varepsilon \nabla G \cdot (\nabla \cdot U) I + \frac{2}{3} \varepsilon \nabla G \cdot (pU) I \\
+ \varepsilon \nabla K_u (ipU) \\
+ \varepsilon K_u \nabla (ipU) + \varepsilon K_u \nabla (\nabla \cdot U) - K_u p \cdot (pU) \\
+ \varepsilon \nabla C (ipW) \\
+ \varepsilon C \nabla (ipW) + \varepsilon C \nabla (\nabla \cdot W) - C p \cdot (W) \\
+ \omega^2 p \rho U + \omega^2 p \rho W = 0. \quad (A9)
\]

Some of the terms in eq. (A9) can be expanded to arrive at

\[
i \varepsilon (\nabla G \cdot U) \\
- \frac{2}{3} i \varepsilon \nabla G (p \cdot U) \\
i \varepsilon \nabla G [(\nabla \cdot p) U + 2p \cdot (\nabla U)] - G p (p \cdot U) \\
i \varepsilon \nabla G [(\nabla \cdot U)p + U \cdot \nabla p + p \cdot (\nabla U)^T] - G p^2 U \\
- \frac{2}{3} i \varepsilon \nabla G (p \cdot U) + (\nabla \cdot U) p + \frac{2}{3} G p (p \cdot U) \\
i \varepsilon \nabla K_u (p \cdot U) \\
i \varepsilon K_u [(\nabla \cdot U)p + p (\nabla \cdot U)] - K_u p (p \cdot U) \\
i \varepsilon \nabla C (p \cdot W) \\
i \varepsilon C [(\nabla \cdot W)p + p (\nabla \cdot W)] - C p (p \cdot W) \\
+ \omega^2 \rho u + \omega^2 \rho w = 0. \quad (A10)
\]

Considering the second governing eq. (16), expanding the derivatives I arrive at

\[
\nabla C \nabla \cdot U \\
C \nabla \cdot U \\
\nabla M \nabla \cdot W \\
M \nabla \cdot W \\
\omega^2 \rho U + \omega^2 \rho W = 0. \quad (A11)
\]

Substituting the differential operators and retaining terms of order $\varepsilon^0$ and $\varepsilon^1$,

\[
i \varepsilon \nabla C \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) \\
+ \varepsilon C \nabla \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) + \varepsilon C \nabla \theta \cdot \left( \nabla \theta \frac{\partial U}{\partial \theta} \right) + C \nabla \theta \cdot \left( \nabla \theta \frac{\partial^2 U}{\partial \theta^2} \right) \\
i \varepsilon \nabla M \left( \nabla \theta \frac{\partial W}{\partial \theta} \right) \\
+ \varepsilon M \nabla \left( \nabla \theta \frac{\partial W}{\partial \theta} \right) + \varepsilon M \nabla \theta \cdot \left( \nabla \theta \frac{\partial W}{\partial \theta} \right) + M \nabla \theta \cdot \left( \nabla \theta \frac{\partial^2 W}{\partial \theta^2} \right) \\
\omega^2 \rho U + \omega^2 \rho W = 0. \quad (A12)
\]

Using the definition of $p$ and the property of the partial derivatives I can write eq. (A12) as

\[
i \varepsilon \nabla C (p \cdot U) \\
i \varepsilon C [(\nabla \cdot U)p + p (\nabla \cdot U)] - C p (p \cdot U) \\
i \varepsilon \nabla M (p \cdot W) \\
i \varepsilon M [(\nabla \cdot W)p + p (\nabla \cdot W)] - M p (p \cdot W) \\
\omega^2 \rho U + \omega^2 \rho W = 0. \quad (A13)
\]

A1 Terms of order $\varepsilon^0 \sim 1$

As noted above, because $\varepsilon$ is assumed to be small, the terms of lowest order are the most significant. To find these terms I substitute the power series expressions for $U$ and $W$, given by (A2) and (A3), into eqs (A10) and (A12). Two equations result, each containing an infinite progression of terms of various orders in $\varepsilon$. If I consider terms of the lowest order in $\varepsilon$, $\varepsilon^0 \sim 1$, I arrive at the two equations

\[
Gp^2 U_0 + \frac{1}{3} G pp \cdot U_0 + K_u pp \cdot U_0 - \omega^2 \rho U_0 \\
+ C pp \cdot W_0 - \omega^2 \rho W_0 = 0. \quad (A14)
\]
and
\[ C \mathbf{p} \cdot \mathbf{U}_0 - \alpha^2 \rho_1 \mathbf{U}_0 + M \mathbf{p} \cdot \mathbf{W}_0 - \alpha^2 \mathbf{p} \mathbf{W}_0 = 0. \]  \hspace{1cm} (A15)

### A2 Terms of order \( \varepsilon^1 \)

Now consider terms of the next lowest order in \( \varepsilon \), those of first order. For the first eq. (A10), I have
\[
i p (\nabla G \cdot \mathbf{U}_0) \\
+ i (\nabla G \cdot \mathbf{p}) \mathbf{U}_0 \\
- \frac{i}{3 \varepsilon} \nabla G (\mathbf{p} \cdot \mathbf{U}_0) \\
+ i G [\nabla \cdot \mathbf{p} \mathbf{U}_0 + 2 \mathbf{p} \cdot (\nabla \mathbf{U}_0)] - G \mathbf{p} (\mathbf{p} \cdot \mathbf{U}_1) \\
+ i G [\nabla \cdot (\mathbf{p} \cdot \nabla) \mathbf{U}_0 + (\nabla \times \mathbf{U}_0) \nabla] - G \mathbf{p} (\mathbf{p} \cdot \mathbf{U}_1) \\
+ i \nabla K_\alpha (\mathbf{p} \cdot \mathbf{U}_0) \\
+ i K_\alpha (\nabla \cdot \mathbf{p} \mathbf{U}_0) + \mathbf{p} (\nabla \cdot \mathbf{U}_0) - K_\alpha (\mathbf{p} \cdot \mathbf{U}_1) \\
+ i \nabla C (\mathbf{p} \cdot \mathbf{W}_0) \\
+ i C (\nabla (\mathbf{p} \cdot \mathbf{W}_0) + \mathbf{p} (\nabla \cdot \mathbf{W}_0) - C \mathbf{p} (\mathbf{p} \cdot \mathbf{W}_1) \\
+ \alpha^2 \rho \mathbf{U}_1 + \omega^2 \mathbf{p} \mathbf{W}_1 = 0, \] \hspace{1cm} (A16)

where I have substituted in the first two terms \( \mathbf{U}_0, \mathbf{U}_1, \mathbf{W}_0, \) and \( \mathbf{W}_1 \) of the power series (A2) and (A3). Similarly, for eq. (A13) I have
\[
i \nabla C (\mathbf{p} \cdot \mathbf{U}_0) \\
+ i C (\nabla (\mathbf{p} \cdot \mathbf{U}_0) + \mathbf{p} (\nabla \cdot \mathbf{U}_0) - C \mathbf{p} (\mathbf{p} \cdot \mathbf{U}_1) \\
i \nabla M (\mathbf{p} \cdot \mathbf{W}_0) \\
+ i M (\nabla (\mathbf{p} \cdot \mathbf{W}_0) + \mathbf{p} (\nabla \cdot \mathbf{W}_0) - M \mathbf{p} (\mathbf{p} \cdot \mathbf{W}_1) \\
\alpha^2 \rho \mathbf{U}_1 + \omega^2 \mathbf{p} \mathbf{W}_1 = 0. \] \hspace{1cm} (A17)

### APPENDIX B: DIFFERENTIAL EQUATIONS FOR \( \mathbf{U}_0 \) AND \( \mathbf{W}_0 \)

In this Appendix, I discuss how to transform the coupled system of linear, first-order differential eqs (82) into two uncoupled second-order equations. First, consider two equations in (82)
\[
\frac{dU_0}{dr} = -\Gamma_{11} U_0 - \Gamma_{12} W_0 
\] \hspace{1cm} (B1)
\[
\frac{dW_0}{dr} = -\Gamma_{21} U_0 - \Gamma_{22} W_0. 
\] \hspace{1cm} (B2)

I can solve eq. (B1) for \( W_0 \) in terms of \( U_0 \) and its derivative
\[
W_0 = -\frac{1}{\Gamma_{12}} \left[ \frac{dU_0}{dr} + \Gamma_{11} U_0 \right]. \] \hspace{1cm} (B3)

Substituting this expression into eq. (B2), carrying out the differentiations, and grouping terms gives
\[
\frac{1}{\Gamma_{12}} \frac{dU_0}{dr} + \frac{d}{dr} \left( \frac{1}{\Gamma_{12}} \right) + \frac{\Gamma_{11}}{\Gamma_{12}} + \frac{\Gamma_{22}}{\Gamma_{12}} \frac{dU_0}{dr} + \frac{d}{dr} \left( \frac{\Gamma_{11}}{\Gamma_{12}} \right) U_0 = 0. \] \hspace{1cm} (B4)

Multiplying eq. (B4) by \( \Gamma_{12} \) and defining the coefficients
\[
\Psi_1(r) = \frac{\Gamma_{11}}{\Gamma_{12}} + \frac{\Gamma_{11}}{\Gamma_{12}}, \quad \Psi_2(r) = \frac{\Gamma_{11}}{\Gamma_{12}} - \frac{\Gamma_{21}}{\Gamma_{12}} + \frac{\Gamma_{11}}{\Gamma_{12}}, \] \hspace{1cm} (B5)

I can write eq. (B4) as
\[
\frac{d^2 U_0}{dr^2} + \Psi_1 \frac{dU_0}{dr} + \Psi_2 U_0 = 0, \] \hspace{1cm} (B7)

a second-order differential equation for \( U_0 \) with variable coefficients. Following a similar procedure I can derive a governing equation for \( W_0 \)
\[
\frac{d^2 W_0}{dr^2} + \Phi_1 \frac{dW_0}{dr} + \Phi_2 W_0 = 0, \] \hspace{1cm} (B8)

where
\[
\Phi_1(r) = \frac{\Gamma_{21}}{\Gamma_{21}} \left( \frac{1}{\Gamma_{21}} \right) = \Psi_1, \quad \Phi_2(r) = \frac{\Gamma_{21}}{\Gamma_{21}} \left( \frac{\Gamma_{22}}{\Gamma_{21}} - \frac{\Gamma_{21}}{\Gamma_{21}} \right) = \Psi_2. \] \hspace{1cm} (B9)

Rather than solving eq. (B7) and (B8) it might be more efficient to solve eq. (B7) for \( U_0 \) and then use eq. (B3) to find \( W_0 \).
