INTRODUCTION
Abdominal aortic aneurysms (AAA) can be classified as inflammatory or non-inflammatory. Non-inflammatory AAAs are characterized by asymptomatic presentation, lack of aneurysmal wall thickening, lack of perianeurysmal fibrosis, and normal erythrocyte sedimentation rate. It is known that inflammatory AAAs can result in obstructive uropathy secondary to retroperitoneal/perianeurysmal fibrosis; however, the incidence of non-inflammatory AAAs resulting in bilateral mechanical compression of the ureters is extremely rare. We present a case report of a patient presenting to the emergency department (ED) for generalized weakness, dark stools, and urinary retention who was found to have two large non-inflammatory AAAs causing ureteral compression with bilateral hydronephrosis.

CASE REPORT
A 77-year-old Caucasian male presented to the ED complaining of generalized weakness, dark stools, and urinary retention who was found to have two large abdominal aortic aneurysms (AAA) compressing his bilateral ureters with associated hydronephrosis and renal insufficiency. In elderly male patients presenting with signs of obstructive uropathy, AAA should be considered as a potential cause. [Clin Pract Cases Emerg Med.2017;X(X):X–X.]

We describe a patient who presented to the emergency department complaining of generalized weakness, dark stools, and urinary retention who was found to have two large abdominal aortic aneurysms (AAA) compressing his bilateral ureters with associated hydronephrosis and renal insufficiency. In elderly male patients presenting with signs of obstructive uropathy, AAA should be considered as a potential cause. [Clin Pract Cases Emerg Med.2017;X(X):X–X.]
significant intra-abdominal pathologies given the patient’s age, comorbidities, presenting symptoms, and findings suggestive of gastrointestinal bleeding, anemia, and renal insufficiency. The CT revealed two large aneurysms: a 9.0 x 9.0 cm infrarenal abdominal aortic aneurysm and a 10.0 x 9.0 right common iliac artery aneurysm. Both aneurysms were increased in size in comparison to a prior study from 2006. There was no evidence of extravasation; however, this study was performed without intravenous contrast due to the patient’s renal failure. Additionally, there was bilateral ureteral compression from the abdominal aneurysms resulting in

What do we already know about this clinical entity?  
Aortic aneurysms are the 14th leading cause of death in the U.S. Common complaints include back, flank, and abdominal pain.

What makes this presentation of disease reportable?  
This patient was found to have two massive aneurysms causing mechanical ureteral compression with bilateral hydronephrosis, which is extraordinarily rare.

What is the major learning point?  
In elderly male patients presenting with signs of obstructive uropathy, aortic aneurysms should be considered as a potential cause.

How might this improve emergency medicine practice?  
Emergency physicians must continue to consider a wide range of differential diagnoses in elderly patients presenting with generalized or atypical abdominal complaints.

**Image 1.** Computed tomography without contrast of the abdomen and pelvis in axial view with an arrow demonstrating a 9 x 9 cm infrarenal aortic aneurysm.

**Image 2.** Computed tomography of the abdomen and pelvis in axial view with arrows demonstrating bilateral hydronephrosis.

**Image 3.** Computed tomography of the abdomen and pelvis in coronal view demonstrates a 9 x 9 cm aortic aneurysm (large arrow) and a 10 x 9 cm right common iliac aneurysm (small arrow).
moderate bilateral hydronephrosis. There was no evidence of an aortoenteric fistula, perianeurysmal fibrosis, or an acute inflammatory process.

The patient was stabilized and transferred to a tertiary care center for deep enteroscopy, bilateral nephrostomy tube placement, and aneurysmal repair. The patient was later discharged to a rehabilitation center, but soon re-admitted for a recurrence of gastrointestinal bleeding.

DISCUSSION

Aortic aneurysms were identified as the primary cause of 10,597 deaths in the United States in 2009. It is the 14th leading cause of death in the U.S. AAAs are described as a focal dilation, 3 cm or greater, of the abdominal aorta with respect to the original artery. Most AAAs occur distal to the renal arteries. AAA risk factors include age of 60 years and greater, smoking history (defined as lifetime use greater than 100 cigarettes), hypertension, male gender, and Caucasian ethnicity. The majority of unruptured aneurysms are asymptomatic and discovered incidentally. The prevalence of symptoms in patients with unruptured AAAs is unknown, but common complaints include back, flank, and abdominal pain. The most common physical exam finding is a pulsatile abdominal mass.

For screening or diagnostic purposes, abdominal ultrasound is the imaging modality of choice (sensitivity of 95% and specificity of 99%); however, CT angiography provides a more detailed assessment of the abdomen preferable for serial monitoring or surgical planning. CT angiography also has the advantage of being able to identify a ruptured AAA. Surgical management is recommended for patients who have AAAs that are symptomatic or greater than 5.5 cm in diameter. In the hemodynamically stable but symptomatic patient with a large unruptured aneurysm, surgical repair can be delayed for medical optimization with the patient monitored in the intensive care unit setting. Traditionally, AAAs were repaired using an open laparotomy approach; however, technological advances now facilitate an endovascular technique, which is associated with better outcomes.

Between 3%–10% percent of AAAs are characterized as inflammatory AAAs (IAAA), which are a distinct entity distinguished by symptomatic presentation, aneurysmal wall thickening, perianeurysmal fibrosis, adherence to surrounding structures, and an elevated erythrocyte sedimentation rate. IAAAs have a 20–40% incidence of ureteral compromise and are well documented as causing bilateral obstructive uropathy. On the other hand, non-inflammatory AAAs have a 0.2% incidence of ureteral involvement and reports of compressive uropathy related to aneurysmal size are exceedingly rare. Upon review of the literature, we found only two previous case reports of non-inflammatory AAAs causing mechanical ureteral obstruction.

CONCLUSION

This case is unique because our patient presented with urinary retention and was found to have renal insufficiency, hydronephrosis, and bilateral ureteral compression from two large aneurysms without preoperative evidence of an inflammatory reaction or fibrotic obstruction. Cases of non-inflammatory AAAs causing mechanical ureteral compression and urinary retention are extraordinarily rare. In elderly male patients presenting with this constellation of symptoms, AAA should be included in the differential diagnosis.
