Supporting Information

ABSTRACT: The solidstate structures of the cobalt–alkyne complexes \((\eta^2\text{-C}_5\text{H}_5)(\text{PPh}_3)\)\((\eta^2\text{-alkyne})\) \((3\text{-TMS}, R = \text{Me}, Ar = \text{C}_6\text{H}_5\); \(3\text{-TIPS}, R = \text{CH(C}_2\text{H}_5\), Ar = p-\text{C}_6\text{H}_4\text{CH}_3\)) and the noncoordinated alkyne (Me_3Si)C=C(C(SO_2Ph)) have been characterized by X-ray crystallography and, in the case of 3-TMS, 6-TMS, and \((\eta^2\text{-C}_5\text{H}_5)\)Co{\((\eta^2\text{-Me}_3\text{Si})\)C=C(C(SO_2Ph))} (5-TMS-calc), by B97D/Def2-TZVPP computational analysis. The phosphine-dissociated complex 5-TMS-calc is determined to be a ground state singlet. Analysis of bond angle and distance metrics, calculated NMR chemical shift data, and molecular orbital analysis provide strong evidence for a four-electron-donor alkyne ligand in 5-TMS-calc. The degree of asymmetry in metal–alkyne bonding, as defined by the Gladysz alkyne-slippage parameter, is dramatically reduced in 5-TMS-calc relative to that in the precursor complex 3-TMS-calc.

INTRODUCTION

Metal–alkyne complexes continue to play a key role in the discovery and development of new organometallic reactions.1–3 The first stable mononuclear cobalt–alkyne complex, \((\eta^2\text{-C}_5\text{H}_5)(\text{PPh}_3)\)Co{\((\eta^2\text{-PhC}=\text{CPh})\)} (1; \(\text{C}_5\text{H}_5 = \text{C}_6\text{H}_5\)). was prepared over 45 years ago by Yamazaki and Hagihara, who also demonstrated the conversion of 1 and additional alkyne to a metallacyclopentadiene complex, 2 (Scheme 1).1a More recently it has been found that unsaturated four-membered metallacycles are also accessible from \((\eta^2\text{-C}_5\text{H}_5)(\text{PPh}_3)\)Co{\((\eta^2\text{-alkyne})\)} precursors via reaction with ethyl diazoacetate. For example, ethyl diazoacetate undergoes a diastereoselective oxidative cyclization with the unsymmetrically substituted alkyne complexes \((\eta^2\text{-C}_5\text{H}_5)(\text{PPh}_3)\)Co{\((\eta^2\text{-Ph(C}_2\text{H}_5\)C=C(C(SO_2Ph))}) \((3\text{-TMS}, Ar = \text{C}_6\text{H}_5\), R = Me; 3-TIPS, Ar = p-\text{C}_6\text{H}_4\text{CH}_3\), R = \(\text{Pr}\)) to generate the metallacyclobutenes \((\eta^2\text{-C}_5\text{H}_5)(\text{PPh}_3)\)Co{\((\eta^2\text{-CH(C}_2\text{H}_5\)C=C(C(SO_2Ph))}) \(4\text{-TMS}, Ar = \text{C}_6\text{H}_5\), R = Me; 4-TIPS, Ar = p-\text{C}_6\text{H}_4\text{CH}_3\), R = \(\text{Pr}\)) with complete control of alkyne regiochemistry (Scheme 1).2

The reactions of \((\eta^2\text{-C}_5\text{H}_5)(\text{PPh}_3)\)Co{\((\eta^2\text{-alkyne})\)} complexes, including the conversion of 3-TMS to 4-TMS, may involve the formation of phosphine-free \((\eta^2\text{-C}_5\text{H}_5)(\text{PPh}_3)\)Co{\((\eta^2\text{-alkyne})\)} (5) intermediates (Scheme 1); however, intermediates of this type have been neither observed nor isolated. It is therefore of interest to elucidate the structures of both the unsymmetrically substituted alkyne complexes, e.g. 3, and the corresponding phosphine-dissociated analogues, 5.

Here we report the first solid-state structures of \((\eta^2\text{-C}_5\text{H}_5)(\text{PPh}_3)\)Co{\((\eta^2\text{-alkyne})\)} complexes bearing unsymmetrically substituted alkynes, 3-TMS and 3-TIPS, as well as computa-
Organometallics

TMS-calc exhibits a singlet ground state which compares to a previous report that \((\eta^3-C_2H_5)_2Co(\eta^2-HC≡CH)\) exists as a ground state triplet.\(^3\) A comparison of the predicted structures for 3-TMS-calc and 5-TMS-calc supports the formulation of 5-TMS-calc as electronically saturated due to involvement of a four-electron-donor alkylene ligand. The degree of alkylene-ligand slippage, as defined by the Gladysz slippage parameter,\(^4\) is moderated significantly upon dissociation of the phosphine ligand from 3-TMS.

RESULTS AND DISCUSSION

Structural Characterization of (TMS)C≡C(SO_2Ph) (6-TMS). In order to determine the structural changes that occur upon alkylene binding to cobalt, X-ray crystallographic and computational analysis of (TMS)C≡C(SO_2Ph) (6-TMS and 6-TMS-calc) (Figure 1 and Table 1) was carried out. Good agreement is found between the experimental and B97D/Def2-TZVPP predicted structures for 6-TMS, with an average C1–C2 triple-bond distance of 1.2104(19) Å in the solid-state structures and a 1.2105 Å distance in the predicted structure (Figure 1). The highly polarized nature of 6-TMS (\(\sigma_c = 0.68, \sigma_m = 0.62\) for SO_Ph; \(\sigma_p = -0.07, \sigma_r = -0.04\) for TMS)\(^5\) is confirmed by the calculated 5.7 D dipole moment. For comparison, the computed dipole moment of (TMS)C≡C(COMe) is 3.6 D.

Synthesis and Spectroscopic Characterization of \((\eta^3-C_2H_5)(PPH_3)Co(\eta^2-(R,Si),C≡C(SO_2Ar))(3-TMS, R = Me, Ar = C_6H_4CH_3; 3-TIPS, R = CH(CH_3)_2, Ar = p-C_6H_4CH_3).\) As described previously,\(^2\) the alkylene complexes 3-TMS and 3-TIPS were prepared from \((\eta^3-C_2H_5)_2Co(\text{PPH}_3)_2\) and the corresponding alkynes 6-TMS and \((\text{PPr}_{3})_2C≡C(SO_2-p-C_6H_4CH_3)\) (6-TIPS), following the procedure developed by Yamazaki and Wakisaki for the synthesis of 1.\(^1\) Table 2 provides a summary of representative spectroscopic data for the cobalt–alkylene complexes 3-TMS and 3-TIPS and, for comparison, the symmetrically substituted alkylene complex 1.\(^1\) In the IR spectra (KBr) of the polarized alkylene complexes, the \(\nu(C≡C)\) stretching frequency occurs at lower wavenumber by 338–348 cm\(^{-1}\) relative to the free alkylene. In comparison, the symmetrically substituted alkylene complex 1 exhibits a larger wavenumber shift of 403 cm\(^{-1}\) relative to that for PhC≡CPh (Raman spectroscopy).\(^1\) Preliminary \(^{13}\)C NMR chemical shift assignments for the alkylene “sp” carbons in 3-TMS were made on the basis of the assumption that back-bonding from cobalt to the carbon bearing the electron-withdrawing sulfone substituent would be greater than back-bonding to the carbon bearing the electron-donating TMS substituent. In the \(^{13}\)C\(^{1}(\text{H})\) NMR spectra \((C_6D_6)\) of the sulfone-bearing alkylene complexes 3-TMS and 3-TIPS, one of the alkylene “sp” carbon resonances exhibits a small downfield shift (\(\Delta \delta \approx 5–7\) ppm) and the other a large downfield shift (\(\Delta \delta \approx 15–17\) ppm), relative to the corresponding chemical shifts in the noncoordinated alkynes. In addition, the downfield resonance exhibits a larger carbon–phosphorus coupling constant than does the upfield resonance.

\(^b\)All IR data (in units of cm\(^{-1}\)) were obtained from thin films on either KBr or NaCl plates, unless otherwise noted.\(^c\)Values in parentheses are the differences in stretching frequency between the free and coordinated alkynes.\(^d\)NMR resonances were referenced to solvent peaks and observed at ambient temperature; \(J_{HC}\) values are given in Hz.\(^e\)Values in parentheses are the chemical shift differences (ppm) of the sp carbons for the coordinated and noncoordinated alkynes.\(^f\)In Nujol.\(^g\)Free alkylene stretch from Raman spectrum.\(^h\)\([M] = CpCo(PPh)_3\).

Figure 1. (top) ORTEP drawings of the two independent molecules in the crystal lattice of Me_3SiC≡CSO_2Ph (6-TMS). (bottom) Ball-and-stick drawing of the computed structure for 6-TMS-calc. Hydrogen atoms are omitted for clarity.
For comparison, \((\eta^5\text{-}C_5\text{-}H_5)(\text{PPh}_3)\text{Co}(\eta^2\text{-}\text{PhC}_\text{≡}C\text{Ph})\) (1) exhibits a \(^{13}\text{C}\) NMR (C\(_6\text{D}_6\)) resonance for the alkyne carbons bound to cobalt at \(\delta 90.4\) (\(J_{\text{CP}} = 8.0\) Hz), which is essentially unchanged from the value for \(\text{PhC}_\text{≡}C\text{Ph}\).\(^{10}\) Thus, the magnitude of the sp carbon chemical shift change that occurs upon complexation to \((\eta^5\text{-}\text{C}_\text{p})(\text{PPh}_3)\text{Co}\) depends on the nature of the alkyne substituents, with electron-withdrawing alkyne substituents exhibiting a much larger downfield shift and larger \(J_{\text{CP}}\) coupling in comparison to the silyl-substituted carbons.

The chemical shift assignments for 3-TMS were confirmed by an HMBC NMR experiment (Bruker DRX600 NMR spectrometer with a TXI 5 mm cryoprobe), which demonstrated a correlation between the TMS carbons and the \(\delta 105.5\) alkyne resonance, but not the \(\delta 118.1\) resonance. In routine \(^{13}\text{C}\) NMR spectra, the silicon-\(29\) satellites for the carbon-\(13\) resonances are difficult to detect; however, a \(^{13}\text{C}\{^{1}\text{H}\}\) NMR spectrum of 3-TMS obtained on a Varian 500 MHz NMR spectrometer equipped with an X-Sens Cold Probe led to the observation of \(J(29\text{Si}^{13}\text{C}) = 40.0\) Hz for the \(\delta 105.5\) resonance. For comparison, the sp carbon bonded to silicon in (TMS)\(\equiv\text{C}(\text{C}_6\text{H}_{13})\) exhibits \(J(29\text{Si}^{13}\text{C}) = 88.7\) Hz,\(^{25}\) and the sp\(^2\) carbon bonded to silicon in ethyl (E)-3-(triethylsilyl)-2-propenoate (Et\(_3\text{SiCH}≡\text{CHCO}_2\text{Et}\)) exhibits \(J(29\text{Si}^{13}\text{C}) = 57.9\) Hz.\(^{76}\)

Crystallographic Analysis of the Cobalt–Alkyne Complexes 3-TMS and 3-TIPS. The only prior solid-state analysis of a \((\eta^5\text{-}\text{C}_5\text{-}H_5)(\text{PPh}_3)\text{Co}(\eta^2\text{-}\text{alkyne})\) complex is that reported by Roewer in 2008 for the symmetrically substituted alkyne complex \((\eta^5\text{-}\text{Cp})\text{Co}(\text{PPh}_3)(\eta^2\text{-}\text{PhC}_\text{≡}C\text{Ph})\) (1).\(^{11}\) For 3-TMS the electron-donating trimethylsilyl and electron-withdrawing sulfone substituents are of similar size, as judged in the context of cyclohexane \(A\) values, which are both 2.5 kcal/mol.\(^{8}\) The relative sizes of TMS (\(\theta = 118^\circ\)) and TIPS (\(\theta = 160^\circ\)) have been addressed in the context of cone angles, with the latter exhibiting a 42° larger cone angle.\(^9\) Although the TIPS group is a slightly better \(\sigma\) donor than TMS, as indicated by a 4.8 cm\(^{-1}\) difference in \(\sigma\) denticity values,\(^9\) the geometric differences in alkyne binding for 3-TMS relative to 3-TIPS are expected to be dominated by steric differences associated with the silyl substituents.

The gross solid-state structural features found in 3-TMS and 3-TIPS are remarkably similar due to analogous conformations about the \(\text{P}–\text{C}, \text{Co}–\text{P},\) and \(\text{C}–\text{S}\) bonds. The conformation of a triphenylphosphine \(\text{P}–\text{C}(\text{ipso})\) bond is conveniently defined by the angle (\(\omega\)) between the normals to the \(\text{Co}–\text{P}–\text{C}(\text{ipso})\) plane and the phenyl ring least-squares plane.\(^{10}\) For most triphenylphosphine complexes, the phenyl ring that occupies the least congested site with respect to the other ligands adopts the smallest value for \(\omega\). Ph\(^{8\text{a}}\) is the triphenylphosphine phenyl...
ring with the smallest $\omega$ value in both 3-TMS ($\omega^A = 57.9^\circ$ (PhA), $57.8^\circ$ calc); $\omega^B = 13.3^\circ$ (PhB, 5.4\textdegree calc); $\omega^C = 70.8^\circ$ (PhC), 71.9\textdegree calc)) and 3-TIPS ($\omega^A = 67.7^\circ$ (PhA); $\omega^B = 3.96^\circ$ (PhB); $\omega^C = 105.6^\circ$ (PhC)) (Figures 2 and 3). The similarity in the Co–P conformations observed for 3-TMS and 3-TIPS is readily apparent from the C1–Co–C2 dihedral angles of −84.14

Figure 3. ORTEP structure of \((\eta^5\text{C}_5\text{H}_5)\)\((\text{PPh}_3)\)\(\text{Co[\eta^2-(TIPS)C\equiv C(SO}_2\text{tol})] (3-TIPS; top), 3-TIPS as viewed down the C1–C2 bond centroid to cobalt axis with the C1–Co–C2 plane highlighted in red (bottom left), and view of 3-TIPS after a 90° rotation of the bottom left structure (bottom right). All hydrogen atoms except those on C12 have been omitted for clarity.

*For a definition of slippage ($\Omega$) see the text and Figure 4. *bThe R1 (S or C) and R2 (Si, C) deviations are from the Co–C1–C2 plane.
and $-92.61^\circ$, respectively. In both complexes the phosphine phenyl ring, Ph$,^\circ$, is positioned below the Co--C2(SiR3) bond, with the greater steric bulk of TIPS relative to TMS resulting in a larger $\omega$ value for Ph$^\circ$ in the 3-TIPS structure ($\Delta \omega = 34.79^\circ$).

The C1–S conformations in 3-TMS and 3-TIPS lead to a folding of the sulfone aryl ring back toward the silyl group, with the closest nonbonded contacts between the sulfone and silyl substituents involving a hydrogen atom of the silyl group and the centroid of the sulfone aryl ring. As seen in Figures 2 and 3, this CH···π distance is 2.86 Å (2.67 Å) for 3-TMS and 2.53 Å for 3-TIPS, which are both well within the sum of the van der Waals radii for hydrogen (1.2 Å) and the aromatic ring (1.9 Å).11 The predicted gas-phase structure, 3-TMS-calc, reproduces this interaction with a CH···π distance of 2.67 Å (Figure 2, top right). Weak CH···π interactions (ca. 1 kcal/mol) are often observed in the crystal packing of organometallic complexes.12 In the case of 3-TMS the similarity of the gas-phase structure to the solid-state structure (Figure 2) indicates that packing forces are not the primary influence on the observed C–S conformations in the solid-state structures.

The geometric parameters associated with metal–alkyne bonding are defined by the C1–C2, M–C1, and M–C2 distances, by the bend-back angles $\alpha$ and $\beta$, which are a measure of the degree to which the alkyne substituents are bent away from the metal, and by the displacement of the alkyne substituents from the M–C1–C2 plane.

The C≡C bond distances in diphenylacetylene (1.924(4) Å) and 6-TMS (1.201(2) Å) are identical within experimental error, as are the corresponding bond distances within 1 (1.278(2) Å), 3-TMS (1.273(3) Å), and 3-TIPS (1.278(3) Å). Pronounced bond length differences are observed for the Co–C1 and Co–C2 bonds in 1 (C1, 1.961(2) Å; C2, 1.955(1) Å) relative to those in 3-TMS (C1, 1.920(2) Å; C2, 2.010(2) Å) and 3-TIPS (C1, 1.919(2) Å; C2, 2.034(2) Å). The observed cobalt–carbon bond distances follow the trend Co–C(SO2Ar) < Co–C6H5 < Co–C(SiR3), which follows the expected inverse correlation with the anticipated degree of cobalt–carbon back-bonding. The steric effect of the TIPS group relative to the TMS group results in a significantly longer Co–C1(TIPS) bond distance relative to the Co–C1(TMS) bond distance.

Both steric and electronic factors may impact the magnitude of the bend-back angle; however, in cases with two large alkyne substituents, such as in 3-TMS and 3-TIPS, $\alpha$ and $\beta$ may also be influenced by steric congestion between the two alkyne substituents. For both complexes of 3, $\alpha$ is substantially larger than $\beta$, which may be attributed primarily to greater backdonation to C1(SO2Ar) than to C2(SiR3). The larger $\alpha$ value for 3-TMS (37°) relative to 3-TIPS (31°) is attributed to greater steric congestion between the sulfone and silyl substituents in the latter complex. For 3-TIPS, $\beta$ is 6° larger than in the case of 3-TMS, as is to be expected on the basis of the relative sizes of the TMS and TIPS groups.

A convenient structural parameter that encompasses many of the individual bond distance and angle metrics associated with alkyne coordination is the *alkyne-slippage* parameter ($\Omega$),

$^a$Values in brackets are for the calculated structures.
previously developed by Gladysz (Figure 4 and Table 3). For metal−alkyne complexes the slippage value would be 0% when the perpendicular from cobalt to the C1−C2 bond intercepts the C≡C midpoint, as in an equilateral triangle (red dashed lines in Figure 4). As expected, $\Omega \approx 0$ for the symmetrically substituted alkyne complex 1. When slippage occurs, the Co−C1−C2 three-membered ring takes the form of a scalene triangle (black triangle in Figure 4). The slippage value would be 100% if the perpendicular shown in blue intersects at C1 or C2. Alkyne slippage is greater in 3-TIPS (28%) than 3-TMS (22%), primarily due to the greater size of TIPS relative to TMS.

**Calculated Structures for** $(\eta^5$-Cp)(PPh3)Co$(\eta^2$-(Me3Si)C≡C(SO2Ph)) (3-TMS-calc) and $(\eta^5$-Cp)Co$(\eta^2$-(Me3Si)C≡C(SO2Ph)) (5-TMS-calc). In order to determine the structural and electronic changes to alkyne coordination that occur upon dissociation of PPh3 from 3-TMS-calc and (\eta^5$-Cp)Co$(\eta^2$-(Me3Si)C≡C(SO2Ph)) (5-TMS-calc; Figures 5−7) were compared. Figure 5 shows the frontier orbitals for 3-TMS-calc, from which one can observe a nodal pattern in the HOMO (left upper panel), as depicted at the bottom of the figure, and the LUMO showing very little orbital density on the alkyne ligand (top right), with a larger component on C2 than on C1. The calculated dipole moments for 6-TMS (5.72 D), 3-TMS (4.92 D), and 5-TMS-calc (4.94 D) are similar, and in the case of the two alkyne complexes they are nearly identical. However, significant differences in alkyne coordination are observed for 3-TMS-calc and 5-TMS-calc. The calculated structure for 5-TMS-calc exhibits a nearly linear Cp−Co−alkyne geometry with a 177.4° Cp(centroid)−Co−alkyne (C1−C2 midpoint) angle, with the degree of alkyne slippage reduced significantly from $\Omega = 22\%$ in 3-TMS-calc to $\Omega = 9\%$ in 5-TMS-calc (Table 3 and Figure 6). A second conformer very close in energy to the one shown for 5-TMS-calc has the phenyl ring rotated away from the TMS group, indicative of a very minor preference for the conformer shown in Figure 6.

Four-electron-donor alkyne ligands typically exhibit longer C1−C2 and shorter C−M bond distances relative to those observed for related complexes involving two-electron-donor alkyne ligands. A comparison of these bond distances for 3-TMS-calc and 5-TMS-calc reveals a significantly longer C1−C2 bond distance ($\Delta = 0.039$ Å) and significantly shorter Co−C1(TMS) ($\Delta = -0.109$ Å) and Co−C2(SO2Ph) ($\Delta = -0.151$ Å) distances in the phosphine-dissociated complex (Figures 6 and 7 and Table 4), all of which are consistent with a four-electron-donor alkyne ligand. In addition, the C1/C2 chemical shifts in the $^{13}$C NMR spectra of four-electron-donor alkyne complexes typically resonate significantly downfield of those for two-electron-donor alkyne ligands. In the case of 5-TMS-calc, the...
calculated carbon-13 chemical shifts for Cl(SO₂Ph) (175.9 ppm) and C₂(TMS) (190.7 ppm) are 63–76 ppm downfield of the corresponding chemical shifts found for 3-TMS-calc (Cl, 113.0 ppm; C₂, 115.0 ppm), once again consistent with a four-electron-donor alkyne ligand.

The formulation of the alkyne ligand in 5-TMS-calc as a four-electron-donor alkyne ligand is further supported by an analysis of the calculated molecular orbitals (Figure 8). Electron donation from the π₅ orbital of the alkyne breaks the degeneracy of the cobalt dₜ and dₜ orbitals, thereby leading to a singlet configuration. The cobalt d orbital (e.g., the dₜ orbital) that accepts the π₅ electrons is also involved as an acceptor of π electrons from the C₃ ligand. The resultant three-orbital—four-electron interaction is described by the LUMO, HOMO-S, and HOMO-15 molecular orbitals. The LUMO is the totally antibonding component of the three-center—four-electron interaction. This orbital shows that a nucleophile would be expected to attack at the alkyne, at the cyclopentadienyl ligand, or at cobalt. For alkyne nucleophiles, attack at cobalt would give bis(alkyne) complexes that are proposed as key intermediates in alkyne cyclotrimerizations. HOMO-5 is alkyne-π and C₃-π in character with a node at cobalt, and HOMO-15 represents the fully bonding descriptor of the three-center—four-electron interaction in which there is an alkyne out-of-plane π interaction with the cobalt dₜ orbital.

The electrophilic HOMO frontier density plots for 3-TMS-calc and 5-TMS-calc (Figure 9, bottom) indicate a greater probability of attack by an electrophile (in the absence of steric effects) at C₂ in 3-TMS-calc, whereas in the phosphine-dissociated analogue 5-TMS-calc there is a greater probability of attack by an electrophile at cobalt. The nucleophilic LUMO frontier density plots for 3-TMS-calc and 5-TMS-calc (Figure 9, top) indicate that the probability of attack by a nucleophile at the alkyne carbons in 5-TMS-calc is greater than in 3-TMS-calc; however, alkyne nucleophiles would be expected to attack 5-TMS-calc at cobalt (as discussed above for the LUMO shown in Figure 8).

**SUMMARY**

The first X-ray crystallographic and computational studies on (η⁵-C₅)(PPh₃)Co(η⁵-alkyne) complexes of unsymmetrically substituted alkynes are reported. The calculated structure of the phosphine-dissociated complex (η⁵-C₅H₅)Co(η⁵-Me₂SiCCl₃SO₂Ph) (5-TMS-calc) reveals the presence of a four-electron-donor alkyne ligand. A comparison of the calculated structures for 3-TMS-calc and 5-TMS-calc demonstrates a significant decrease in the alkyne slippage parameter, which may be attributed to the effect of electron donation from the π₅ orbital to cobalt. Studies are in progress to determine if this phenomenon is a general one for other four-electron-donor alkyne ligands bearing polarizing alkyne substituents.

**EXPERIMENTAL SECTION**

**Computational Methods.** The conformational analyses of the molecular systems described in this study, including structural and orbital arrangements as well as property calculations, were carried out using the GAMESS**¹⁴** and GAUSSIAN09**¹⁵** software packages. Structural computations of all compounds were performed using the B97-D dispersion enabled density functional method, with an ultrafine grid, in accord with the ansatz proposed by Grimme.**¹⁶,¹⁷** The B97-D exchange-correlation functional is a special reparameterization of the original B97 hybrid functional of Becke,**¹⁸** which is more neutral to spurious dispersion contamination in the exchange part than the original functional. The Def2-TZVPP basis set**¹⁹** was used for all calculations. Full geometry optimizations were performed and uniquely characterized via second derivatives (Hessian) analysis to determine the number of imaginary frequencies (0 = minima; 1 = transition state), and effects of zero-point energy. From the fully optimized structures, single-point NMR computations were performed with the class II NMR methodology, CSGT,**²⁰** and calibrated against TMS. Visualization and analysis of structural and property results, including electrophilic (HOMO) and nucleophilic (LUMO) frontier density plots, were obtained using Avogadro**²¹** and WEBMO.**²²**
