A 33 year-old female presented to the emergency department (ED) with two weeks of diffuse abdominal pain, right flank pain, and a slowly enlarging right inguinal mass. She had no associated fever, chills, nausea, vomiting, or diarrhea. She was evaluated by her primary care physician, and an inguinal ultrasound was obtained prior to referral to the ED. On arrival in the ED, her vital signs were unremarkable, and she was afebrile. On exam, there was no abdominal tenderness, and a 2cm x 2cm non-reducible, mildly tender right inguinal mass was noted. A bedside ultrasound (Figures 1 and 2) was performed in the ED. [West J Emerg Med. 2014;15(7):822–823.]

**DIAGNOSIS**

*Amyand’s Hernia:* Named for Claudius Amyand, sergeant-surgeon to King George II of England, Amyand’s Hernia is an appendix within an inguinal hernia. In the index case, he is credited with performing the first successful appendectomy in 1735, on an eleven year-old boy with this condition. Although relatively rare, (0.13% of cases of acute appendicitis occur in external hernias), it is important to consider this diagnosis in the setting of abdominal pain with an associated inguinal mass. In addition, Amyand’s Hernia may mimic an acute scrotum in cases of appendiceal rupture after a period of incarceration. In this particular case, bedside ultrasound demonstrated a non-compressible 7.4 mm tubular structure within a hernia sack (Figures 1 and 2), representing the appendix. The patient was taken to the operating room for open appendectomy and femoral hernia repair. She was discharged without any complications the following day.
