An electron paramagnetic resonance study of the binding of manganese to ribulose 1,5-diphosphate carboxylase— inhibition by magnesium

D. K. CHU, R. CHANG*, and L. E. VICKERY**
Laboratory of Chemical Biodynamics, Lawrence Berkeley Laboratory, University of California, Berkeley, California 94720 (U.S.A.)

SUMMARY

Electron paramagnetic resonance (EPR) was used to measure the extent of binding of Mn$^{2+}$ to ribulose 1,5-diphosphate carboxylase purified from spinach leaves. In the Mn$^{2+}$ concentration range 0.60 mM to 0.04 mM only a single Mn$^{2+}$ binding site having $K_d = 0.06$ mM was observed. Mg$^{2+}$ was found to competitively inhibit the binding of Mn$^{2+}$, and $K_d = 0.54$ mM was calculated for Mg$^{2+}$.

D-Ribulose 1,5-diphosphate carboxylase (3-phospho-D-glycerate carboxylase [dimerizing] EC 4.1.1.39) catalyzes the carboxylation of RuDP to yield two moles of 3-D-phosphoglycerate in the primary carbon fixation step of photosynthesis. The reaction has an absolute requirement for a divalent metal cation$^1$, and it has been suggested that control of metal ion activation might play a role in the regulation of the enzyme’s activity in vivo$^2$. Little is known, however, about the stoichiometry of

the metal ion-enzyme interaction, the nature of the groups on the protein involved in the interaction, or the mechanism of the activation. In fact, the only cases where binding of metal ions to the enzyme has been studied involved inactive ternary complexes of the enzyme with a substrate analogue or complexes with cyanide. Putative evidence for the existence of an enzyme-CO$_2$-Mg$^{2+}$ has also been reported.

We have used electron paramagnetic resonance techniques to study the binding of Mn$^{2+}$ to the enzyme. Free Mn$^{2+}$ ion in solution has an intense isotropic EPR spectrum, but the EPR of Mn$^{2+}$ bound to small molecules and proteins is often broadened and undetectable providing a convenient means of measuring binding constants. Electrophoretically pure RuDP carboxylase was isolated from spinach leaves as previously described with the following modifications: the heating step was no longer used and 0.02 M sodium phosphate, pH 7.4, replaced tris-HCl and Mg$^{2+}$ during purification. Freshly prepared enzyme was concentrated by precipitation with ammonium sulfate, resuspended in 0.05 M Tris, pH 7.8, and exhaustively dialyzed against this buffer. Protein concentrations were determined spectrophotometrically, taking the absorbancy at 280 nm to be 0.61 (cm-mg/ml)$^{-1}$ and assuming a molecular weight of 557,000. X-band EPR spectra were recorded on a Varian E-3 spectrometer.

When RuDP carboxylase was added to solutions of Mn$^{2+}$ in buffer a quantitative reduction in the intensity of the Mn$^{2+}$ EPR signal was observed. No changes in the EPR spectrum of the aquo-complex appeared, and no evidence for any new signal was obtained. A titration of the

enzyme was made assuming that the heights of the hyperfine components in the first derivative EPR spectrum are proportional to the concentration of free Mn$^{2+}$. The results of three experiments, using different enzyme preparations and concentrations, are presented in the form of a Hughes-Klotz plot$^7,10$ in Fig. 1. In the absence of competing divalent cations the data fit a single straight line reasonably well. The x and y intercepts are equal to the reciprocals of the dissociation constant and the number of binding sites, respectively. Within the Mn$^{2+}$ concentration range used, 0.80 mM to 0.04 mM, K$_d$ $\approx$ 0.06 mM and n = 1. When Mg$^{2+}$ was added to solutions of enzyme and Mn$^{2+}$, an increase in the free Mn$^{2+}$ EPR signal was observed (Fig. 1). In the presence of 0.6 and 1.2 mM Mg$^{2+}$ the K$_d$ for Mn$^{2+}$ increased to 0.12 mM and 0.18 mM, respectively, while n remained equal to 1. Assuming competitive binding of the two cations, K$_d$ for Mg$^{2+}$ can be determined$^{11,12}$. The results of separate calculations at each Mn$^{2+}$ and Mg$^{2+}$ concentration are shown in Table I. The average value for K$_d$(Mg$^{2+}$) = 0.54 mM.

The dissociation constant for Mn$^{2+}$ in the absence of Mg$^{2+}$ measured in this work is close to the Michaelis constant for Mn$^{2+}$, K$_m$ = 0.04 mM, determined by others$^0$. This suggests that the binding observed might yield the active enzyme-metal complex required for catalysis. The stoichiometry of the Mn$^{2+}$-enzyme interaction observed here, however, is unexpected. RuDP carboxylase is composed of sixteen subunits of molecular weight of approximately 12,000 and 56,000 daltons in a 1:1 molar ratio$^{13}$. Moreover, there seem to be eight binding sites for RuDP$^3$. The presence of a single Mn$^{2+}$ binding site could be explained by a unique site linking several subunits, by an undetected difference in one subunit,
or by the existence of an additional subunit. This Mn$^{2+}$ binding site may be related to the single Cu$^{2+}$ binding site which has been reported$^3$ since our preparations of the enzyme do not appear to contain copper (Vickery, Chang, and Chu, unpublished).

The dissociation constant determined for Mg$^{2+}$ competition with Mn$^{2+}$ binding is significantly lower than the Michaelis constant for Mg$^{2+}$, $K_m = 1.1 \text{ mM}$$^9$. Thus, this binding may not be limiting for activation of the enzyme. The ability of Mg$^{2+}$ to compete with Mn$^{2+}$ in this concentration range might compensate for the lower $K_m$ for Mn$^{2+}$ and rule out the possibility of Mn$^{2+}$ activation of the enzyme in vivo. Further experiments utilizing the Mn$^{2+}$ EPR probe can be designed to determine the effects of temperature, pH, CO$_2$, RuDP and competing ions on the metal-enzyme interaction.

This work was supported, in part, by the U. S. Atomic Energy Commission.
