In a previous letter we reported a hydrogen bubble-chamber experiment in which the existence of an excited 1520-Mev hyperon was established. Moreover, a study of the angular distributions and polarizations of Σ hyperons from the reaction \( K^- p \rightarrow \Sigma^+ \pi^- \) in the vicinity of this resonance showed the KΣ parity to the negative. A further study of this reaction permits us to determine the asymmetry parameter \( a \) in \( \Sigma^\pm \) decay by means of their decay asymmetries. The \( a \) for \( \Sigma^+ \rightarrow n\pi^+ \) (called \( a_4 \)) and \( \Sigma^0 \rightarrow p\pi^0 \) (called \( a_0 \)) have already been well established, and our measurements are in good agreement with the published values, although statistically less accurate. The \( a \) for \( \Sigma^- \rightarrow n\pi^- \) has however resisted measurement via the \( \Sigma^- \) decay asymmetry due to uncertainty in \( \Sigma^- \) polarization. Since the procedure described in reference (2) yields a relatively precisely specified and rather large value for the \( \sin \theta \cos \theta \) term in \( \Sigma^- \) polarization over the \( K^- \) momentum range 350 to 450 Mev/c, we have been able to determine the helicity \( a \sim -0.16 \pm 0.21 \).

Figure 1 shows the measurement as a function of momentum of 
\[
(aP)\sin \theta \cos \theta
\]
for the reaction \( K^- p \rightarrow \Sigma^- \pi^+ \), where \( \theta \) is the c.m. angle between the \( K^- \) and \( \pi^+ \), and \( P \) is the average value of the \( \Sigma^- \) polarization over the angular interval \( 0.95 > |\cos \theta| > 0.30 \) as described in reference 2. The solid curve shows the value of \( P \) for this reaction, calculated using a least-squares fitting program to determine the S-, P-, and D-wave amplitudes. These
amplitudes are essentially those of reference 2, except that the full width of the $D_{3/2}$ resonance is now $\Gamma = 25$ Mev. The dashed curve shows a maximum-likelihood fit to $\alpha P$ over the previously noted momentum range, resulting in the value of $\alpha_-$ quoted above. Similar procedures applied to $\Sigma^+$ and $\Sigma^0$ decays yield the values shown in column 2 of Table 1. The uncertainties are statistical and correspond to standard deviations for a gaussian likelihood function ($e^{-1/2}$ points on the likelihood curve). The uncertainties in the calculated $\Sigma$ polarization are small relative to this. From our experiment, $\alpha_+$, $\alpha_-$, and $\alpha_0$ all have the same sign. The overall sign is determined by the sign of $\alpha_0$ as measured by Beall et al. Column 3 gives $\alpha$ as measured by other experimenters.

We shall now describe these asymmetries in terms of the $|\Delta T| = 1/2$ triangular relationship of Gell-Mann and Rosenfeld. In their notation,

$$N_+ + \sqrt{2} N_0 = N_+^0, \quad N_-, \quad N_0$$

where $N_{\pm,0}$ signifies the decay amplitudes for $\Sigma_{\pm,0}$. For spin-1/2 hyperons decaying into $S$ and $P$ states with amplitudes $S$ and $P$, we have $N = S + P$ and

$$\alpha = \frac{2\text{Re} S^0 P}{|S|^2 + |P|^2} \approx \frac{2 SP}{S^2 + P^2}. \quad (1)$$

Here we have used time-reversal invariance to relate the phases of these amplitudes to the $wN$-scattering phase shifts. These phase shifts are listed in reference 3 and are seen to be small. Taking the amplitudes to be real (the resulting error is small relative to experimental uncertainties), one then describes the various decay amplitudes as vectors in an $S$-$P$ plane. The magnitudes of the vectors are determined from the three decay rates.
The directions are obtained from Eq. (1) by expressing $a = \sin 2\theta$,
where $\theta$ is the angle with respect to the coordinate axis. Two ambiguities
remain—the labeling of the $S$ and $P$ axes.

Using the combined values for the helicities $a$ listed in Table I, we
construct Fig. 2. The two directions for $N_0$ arise from $|a_0|$ being less than
one, corresponding to $S/P$ greater or less than one. For $a_0 = -1$, the triangle
would close well within experimental errors, and the triangular relationship
given by the $|\Delta T| = 1/2$ rule would hold. The inconsistency with the $|\Delta T| = 1/2$
rule lies between two and three standard deviations.

3. The decay asymmetry is written as $1 + a \Sigma \cos \phi$, where $\phi$ is the angle between the hyperon polarization, $\Sigma$, and the nucleon direction. This convention has the merit of having the nucleon helicity equal to the decay asymmetry parameter. The more usual, but not universal, convention of following the pion leads to an annoying minus sign relating the helicity to the asymmetry parameter.
7. See reference 5. The value we quote uses the $|\Delta T| = 1/2$ rule, but in only a very weak way involving the $\pi N$ phase shifts. We have adjusted their uncertainties to correspond to standard deviations.
9. W. H. Humphrey and R. R. Ross, Low-Energy Interactions of K⁻ Mesons in Hydrogen, Lawrence Radiation Laboratory Report UCRL-10018, January 12, 1962 (to be submitted to Phys. Rev.). The mass difference has been accounted for to first order by dividing the decay rates by the phase-space factor $P/E$ to obtain $|N|^2$. If we assume the $|\Delta T| = 1/2$ rule, these decay amplitudes alone show that the triangle is nearly a right triangle (94±5 deg).
