ACKNOWLEDGEMENTS

I am extremely grateful for the opportunity to conduct this research under the guidance of my advisor, Dr. Vistasp Karbhari. Without his support and academic passion, I would not have achieved what I have today. I would like to thank my committee members Prof. Gilbert Hegemier and Prof. Yu Qiao for their personal commitments and technical contributions.

Thanks to all of members of my research group, friends and family for support and help throughout my studies.

The research for this thesis was funded by Caltrans, for which I am thoroughly appreciative.
Development of a Rapid Design Procedure for Emergency Repair of Bridge Columns Using Fiber-Reinforced Polymers

by

Susan E. Slater

Master of Science in Structural Engineering

University of California, San Diego, 2008

Professor Vistasp Karbhari, Chair

Fiber reinforced polymers (FRP) are increasingly used for seismic retrofit of undamaged bridge columns. The addition of a confining jacket increases overall strength and ductility of the column. However, FRPs can also be used for repair of a damaged bridge column after a seismic event. This research project explores the application of FRPs for retrofit of damaged circular columns. A decision tree for the emergency repair of damaged columns is presented. The decision tree aids field engineers first in assessing the extent of damage to a column from a seismic event, impact or any other source of damage. Once the level of damage is specified, the decision tree can be used to determine the feasibility of FRP retrofitting. If an FRP jacket is a viable option, suggested simplified design guidelines can be used to determine the design thickness and type of required FRP jacket that should be used for the emergency repair of the column. The project included detailed evaluation of existing confining models and a proposition
of a new model based on a large database of previously tested specimen columns. Several design equations were also evaluated in order to find the most accurate yet simple approach for the design thickness. The end result is a step-by-step simplified guide for engineers to use in the field for emergency repair of damaged circular bridge columns.
Chapter 1

Introduction

1.1 Introduction

Fiber reinforced polymers (FRPs) are used extensively for seismic retrofit of columns to enhance the ductility of the column and increase the axial load carrying capacity. The effectiveness of this method has been widely studied and proven through full scale laboratory testing and field installation. A variety of fabrication techniques have been implemented with success including wet layup, winding with wet tow or prepreg tow, wrapping of prepregs and adhesive bonding of prefabricated sections.

Seismic retrofit focuses on bridges that are currently undamaged, but deemed deficient for seismic events. There has been little research into the repair of already deficient columns using FRP systems. There is a need for rapid methods that enable emergency repair in order to maintain use of high priority bridges after a seismic event. It is noted that although the seismic retrofit concepts are applicable for emergency repair, there is a lack of availability of guidelines and testing for this application.

1.2 Research Objectives and Motivations

The main objective for this research is to create guidelines for the emergency repair of damaged bridge columns. This project will lead to guidelines that can be used by field engineers to assess whether emergency repair using FRP materials is a viable option, and if so, steps to be taken to design and implement the repair system. The
motivation for the guidelines is to generate a rapid response for repair of damaged columns in order to maintain access to key bridges after a seismic event.

There are also several motivations for specifically using FRP as opposed to the more traditional steel jackets for repair. FRP allows for a more rapid installation process. Steel jackets would need to be manufactured and then installed; whereas, wet layup based fabrication of FRP jackets enables the agency to be ready to implement the repair at any moment. Rapid installation at any time is crucial for emergency repair. FRP wet layup also allows for ease of tailorability to specific column geometries, since the fabric can conform to any shape of column. The installation process also does not require large machinery, which allows for implementation in more restricted areas when compared with steel jacketing. There are also potential long term advantages for using FRP. There is a potential for enhanced durability and decreased maintenance, due to the materials non corrosive quality.

1.3 Literature Review

It is well known the effectiveness of using FRP jackets for seismic retrofit and the concept has been used with success in the field extensively. However, there has been considerably less research of the use of FRP jackets for repair of damaged or corroded columns. This section will review important research that has been conducted in the topic of column repair with FRP jackets. There will also be a review of confinement models for FRP jackets in Chapter 3 and a review of guidelines for design of FRP jackets in Chapter 4.
1.3.1 Saadatmanesh et al. (1997)

Saadatmanesh et al. [37] performed experimental tests on reinforced concrete columns with earthquake like damage repaired with GRRP jackets. Unidirectional E-glass fiber in a polyester matrix were wrapped around damaged sections of concrete columns. Four 1/5 scale columns with single bend and a strong footing were used. The specimens consisted of two circular columns and two rectangular columns. Each column corresponded to certain design deficiencies often seen in the field, such as inadequate transverse reinforcement or started bar lap length. The original columns were tested to failure and damaged included debonding of the starter bars, spalling and crushing of concrete, local buckling of the longitudinal reinforcement, yielding of the stirrups and separation of the main bars from the concrete core. The columns were then repaired using 0.8 mm of FRP jacket. This thickness was chosen based on the amount of confining pressure needed to return the column to current design standards.

The repaired columns were subjected to the same loading cycle as the original columns. It was observed that the repaired columns performed at least as well or better than the original columns. In particular, the repaired columns showed a significant increase in the level of strength and ductility achievable. The repaired columns exhibited a ductility level of between 4 and 6, whereas the original columns had ductility levels as low as 1.5. In addition, the repaired columns showed a slower rate of stiffness degradation with each cycle when compared with the original column stiffness degradation rate. It was also observed that the repaired columns showed much larger lateral displacements at low load levels, which is most likely due to the existing damage.
Saadatmanesh et al. [37] concluded that FRP wraps are effective in restoring the flexural strength and ductility capacity of concrete columns.

1.3.2 Ma and Xiao (1999)

Ma and Xiao [29] investigated the use of prefabricated GFRP jackets to repair circular bridge columns that have poor lap slice details. A ½ scale column was used for testing, which was built to the pre-1971 design standards; and therefore, possessed certain deficiency for seismic design, including inadequate lap splice lengths. The as-built column was tested to failure, with a failure mode of bond failure in the plastic hinge region. The column was then repaired by injecting epoxy in the damaged plastic hinge region and then wrapping the column with five layers of prefabricated GFRP shells, which has a thickness of 2.5 mm per layer.

The repaired column was subjected to a simulated earthquake load. An increase in ductility from 4 to 6 was observed. Ma and Xiao [29] concluded that GFRP prefabricated shells are effective in repairing columns and show an improved stiffness, as well as ductility and energy absorption capacities.

1.3.3 Lee et al. (2000)

Lee et al. [25] conducted experimental tests on large scale reinforced concrete columns, subjected to an accelerated corrosive environment. A total of seven large scale concrete columns were tested. Five of the columns were subjected to accelerated corrosion. The accelerated corrosion was applied by exposing the concrete columns to sodium chloride, applying an electrical current to the steel reinforcement and subjecting the columns to wet-dry cycles. The accelerated corrosion resulted in steel loss and
cracking and spalling of the concrete. Three columns were repaired using CFRP sheets and the remaining four columns were used as control specimens.

The corrosion damaged columns were repaired using a CFRP jacket. The repaired columns were then tested to failure or subjected to further accelerated corrosion.

Lee et al. [25] observed large improvements in the repaired column strength and in the rate of additional corrosion. The repaired columns showed an increase in load carrying capacity of up to 28% as compared to the un-repaired corroded column. It was also observed that the rate of additional corrosion was decreased by 50%. In addition, the columns subjected to further corrosion showed no loss of strength or stiffness and only a small reduction in ductility as compared to the repaired column.

1.3.4 Li et al. (2003)

Li et al. [26] tested eight circular reinforced concrete columns repaired with FRP jackets. The columns were designed to conform to all design recommendations put forth in ACI 318 [2]. The columns were then subjected to tensile tests until failure occurred. A tensile test was used as opposed to a more realistic bending and compression test because the damage and crack are more controllable with the tensile test.

Three damaged columns were then repaired using wet layup of four layers of GFRP fabric with an epoxy resin. Another three columns were repaired using a prepreg GFRP jacket. Two columns were left un-repaired to use as control specimens. The columns were then subjected to a uniaxial compression test to determine the modulus of elasticity and the compressive strength of each column. It was concluded that the FRP jackets significantly increased the compressive strength of the damaged column. Li et al.
[26] also concluded that the prepreg jacketing system obtains a higher modulus of elasticity than the wet layup approach.

1.3.5 Tastani et al. (2006)

Tastani et al. [46] tested a total of 12 square columns. Nine of the columns were constructed according to the old standards with inadequate transverse reinforcement. The remaining three columns were designed with modern practices. The columns were subjected to compression loads until the concrete cover spalled away. The columns were then repaired using either a GFRP or CFRP jacket of 1-2 layers thickness.

Tastani et al. [46] observed that the axial load increased in the repaired columns when compared with the control columns that were un-repaired. There was also determined to be an increase in the deformation capability. Tastani et al. [46] also suggested that the effect of increase in strength and ductility was more pronounced in the CFRP jackets as opposed to the GFRP jackets. In all cases, the column failure mode was rupture of the FRP jacket at the corners of the column. This was followed by buckling of the longitudinal reinforcement in the columns constructed from old design standards.

1.3.6 Vosooghi and Saiidi (2008)

Vosooghi and Saiidi [50] tested a damaged ¼ scale two span bridge, comprised of two circular columns. The columns were damaged to a level corresponding to damage state 4, which will be discussed in greater detail in Chapter 2. At this damage state, concrete has spalled severely and reinforcing bars are visible. This damage state also corresponded to an approximate drift of 8%.
The concrete columns were repaired using CFRP jackets. The design thickness was determined using the Caltrans Memo 20-4 [5] design approach, which will be discussed in more detail in Chapter 4. The end design used 2 layers of CFRP within the plastic hinge region and one layer on the remaining column.

The repaired columns were tested using three dynamic tests, eight static tests and four white noise tests. The dynamic tests were the same as on the original column prior to repair.

Vosooghi and Saiidi [50] concluded that repair design was effective in restoring strength and ductility to the damaged column. It was observed that the strength, ductility capacity and drift capacity were restored to at least that of the original column. It was determined that 87% of the stiffness was restored.

1.4 Scope of Research

This research is aimed at three specific tasks. The first task is to characterize the level of damage to a column and establish which degrees of damage can be repaired using FRP jackets. This task will allow field engineers to easily assess and characterize the amount of damage to the column through visual inspection.

The second task is to develop detailed guidelines for the emergency repair of the column. This includes a comprehensive review and analysis of existing guidelines including confining models and design codes.

The final result will be the development of the bases for a decision tree, which will guide the engineer step-by-step in assessing the damage in the column and then
choosing an appropriate thickness of the FRP jacket that would be required to sufficiently repair the column.

This research is focused on seismic damage, but is also applicable with minor modifications to a wide range of damage causes including impact damage, design flaws or corrosion damage. Although the general procedure is applicable to the full-range of geometries, this research will only consider circular columns due to their frequency in existing structures and their relative efficiency of confinement.
Chapter 2

Damage Analysis

2.1 Introduction

The current design philosophy for seismic design of bridges is a “no-collapse” approach. The designs allow for significant nonlinear response, which can result in considerable amounts of damage including concrete cracking and spalling, yielding of reinforcing bars and possibly rupture of some reinforcing bars. Therefore, after seismic events, the column is damaged, but theoretically repairable. Visual classification of the damage to a column is an important first step in the repair process. Classification of the extent of damage can correspond to the status of the column and the method of repair.

Typically field engineers use visual inspections to determine the degree of damage to the column. Five damage states characterized from their associated visual characteristics are presented in this chapter. In addition, average response parameters associated with each damage state, such as strain in the reinforcing bars are presented and compared with experimental results.

2.2 Damage States

The American Concrete Institute (ACI), Building Research Establishment, Ltd. (BRE), Concrete Society and International Concrete Repair Institute jointly publish standards for concrete repair. The result is the Concrete Repair Manual, which is currently in the second edition released in 2001 [3]. Within the manual are standards for visually inspecting damaged concrete and the corresponding damage states. The same
damage states are adopted for this research in order to maintain consistency within standards for inspection and characterization.

The manual divides the damages states into five distinct damages states (DS), DS-1 through DS-5. Damage state DS-1 corresponds to very slight damage with minimal cracking, characterized by flexural cracks and no visible spalling. Damage state DS-2 has slight damage and occurs when first spalling and shear cracks are visible. Damage state DS-3 is moderate damage and is associated with extensive cracks and spalling. Damage state DS-4 is severe damage, in which the spiral and longitudinal reinforcing bars become visible and large cracks, holes and spalled areas are observed. Damage states DS-5 corresponds to very severe damage and is associated with imminent failure and cracks propagating within the concrete core. Table 2.1 details the specific visual characteristics associated with each damage state as referenced in the Concrete Repair Manual, Second Edition. [3]

In conjunction with this project, UNR conducted tests on circular reinforced concrete columns. Columns were damaged to levels corresponding to each damage state
through the visual inspection descriptions. Figures 2.1 through 2.5 show the visual characteristics associated with each damage state.

Figure 2.1- Damage state DS-1, flexural cracks.

Figure 2.2- Damage state DS-2, spalling and shear cracks.
Figure 2.3- Damage state DS-3, extensive cracking and spalling.

Figure 2.4- Damage state DS-4, spiral and longitudinal reinforcing bars visible.
2.3 Estimated Response Parameters

The two important response parameters considered for this project are the strain in longitudinal reinforcing bars and the strain in the spiral hoop reinforcing bars. Strain in the reinforcing bars is important in determining possible repair methods because if the longitudinal bars reach a strain at which they could rupture, repair via FRP jackets is not an appropriate means of repair. Likewise, if the spiral hoops are at a strain level at which they yield, there is likely damage to the concrete core; therefore, repair with an FRP jacket is not appropriate.

The strain levels in the reinforcing bars can be estimated based on the visual classifications associated with each damage state. It is expected that the longitudinal reinforcing bars will yield once flexural cracks are visible, corresponding to DS-1. The longitudinal bars yield at this point because a plastic hinge is formed causing the bars to yield. For Grade 50 steel, the yield strain is between 0.002 and 0.0023. The longitudinal bars are not expected to reach the rupture strain, since ruptured bars are not observed in
any of the damage state classifications. The rupture strain for Grade 50 steel is approximately 0.35.

Similarly, the spiral reinforcing bars would be expected to yield once the cracks in the concrete propagate into the column core, which corresponds to DS-5. Once the spiral reinforcement yields, FRP jacket repair is not possible.

The collaborators for this project at UNR measured the response parameters at each damage state level. Nineteen columns, containing Grade 50 steel reinforcement were subjected to seismic forces, which caused varying degrees of damage. Each column was visual inspected and classified into one of the five damage states described above. Response parameters, including maximum strain in longitudinal reinforcing bars and maximum strain in spiral reinforcing bars were measured in correlation with each damage state. Table 2.2 shows the range of strains associated with each damage state. The range was determined using the average value measured plus and minus the standard deviation.

</tbody>
</table>

The yellow highlighted strains correspond to steel that has yielded (i.e. strain greater than 0.002). These tests verify that the longitudinal reinforcement yields at DS-2
and that the spiral reinforcement yields at DS-5. Therefore, repair using FRP wet layup jackets is not an appropriate option if the column is characterized as DS-5.
Chapter 3

Confinement Models

3.1 Introduction

FRPs are gaining popularity for seismic retrofitting purposes. Even still a reliable and accurate model of concrete confinement is not agreed upon among experts. Many models of confined strength of concrete and associated strain have been proposed dating back to Richart et al.’s [35] original model in 1928 to the present day. FRP is an attractive alternative to steel jacketing because of its high strength-to-weight ratio and resistance to corrosion. FRPs are also appealing due to the relatively ease of construction through wet-layup and versatility of column geometry that can be easily wrapped.

The objective of this chapter is to review existing models for concrete confinement, compare results with experimental data, and finally propose a new model based on the experimental data.

A confined column has increased strength due to the passive restraint provided by the jacket, which restricts the transverse dilation of the column. Circular columns have the most efficient section for confining; therefore, this paper will focus on models and experimental data relating to circular columns only. For a circular column, the lateral confining pressure from the FRP jacket, $f_i$ can be evaluated using a free body diagram as shown in Figure 3.1,
The forces from the free body diagram can be solved for, which results in the following relation:

\[ f_i = \frac{2f_f t_f}{D} \]  

Equation 3.1

where \( f_f \) is the tensile strength of the FRP in the hoop direction, \( t_f \) is the thickness of the FRP jacket, and \( D \) is the diameter of the confined concrete.

Since FRP behaves elastically, the inward pressure due to a jacket increases continuously. In contrast, steel provides a constant lateral confining pressure. Many early confinement models are based on the response of steel jacketed specimens. These models inaccurately model the elastic behavior of FRP. [35, 30, 9] In this paper, several models will be evaluated and compared to experimental data.
3.2 Review of Existing Models

3.2.1 Richart et al. (1928)

Richart et al. [35] performed tests on concrete cylinders with steel spiral reinforcement. The cylinders were subjected to confining hydrostatic pressure. Experimental results showed that the confining action increased the peak strength of the concrete as well as the ultimate strain. It was concluded that the strength of confined concrete at failure, $f'_{cc}$, could be expressed as a linear function of the lateral confining pressure, $f_l$, as follows:

$$f'_{cc} = f'_{co} + k_1 f_l$$  \hspace{1cm} \text{Equation 3.2}

where $f'_{co}$ is the strength of the unconfined concrete and $k_1$ is the confinement effectiveness coefficient. Richart et al. [35] recommend using $k_1 = 4.1$.

Richart et al. [35] also proposed a model for the longitudinal strain of the confined concrete at failure, $\varepsilon_{cc}$:

$$\varepsilon_{cc} = \varepsilon_{co} \left(1 + k_2 \frac{f_l}{f'_{co}}\right)$$  \hspace{1cm} \text{Equation 3.3}

where $k_2 = 5 k_1$ and $\varepsilon_{co}$ is the longitudinal strain of the unconfined concrete at failure, which is typically assumed to be 0.002.

3.2.2 Fardis and Khalili (1982)

Fardis and Khalili [12] were the first to consider effects of concrete confinement due to FRP. Concrete cylinders were wrapped with glass FRP (GFRP)
and then subjected to compression tests. Fardis and Khalili [12] adopted the general formula for strength of concrete as follows:

\[ f'_{cc} = f'_{co} \left[ 1 + k_1 \frac{f_{l}}{f'_{co}} \right] \]  

Equation 3.4

From the test results, it was proposed that the coefficient of confinement, \( k_1 \), have the following value for a specimen wrapped in FRP:

\[ k_1 = 3.7 \left( \frac{f_{l}}{f'_{co}} \right)^{-0.14} \]  

Equation 3.5

This confinement coefficient yielded the following expression for the strength of confined concrete:

\[ f'_{cc} = f'_{co} + 3.7 \left( \frac{f_{l}}{f'_{co}} \right)^{0.86} \]  

Equation 3.6

For the corresponding ultimate strain at failure, Fardis and Khalili [12] suggested:

\[ \varepsilon_{cc} = \varepsilon_{co} + 0.0005 \left( \frac{E_{f} t_f}{D \cdot f'_{co}} \right) \]  

Equation 3.7

where \( E_f \) is the modulus of elasticity of the FRP jacket.

3.2.3 Mander et al. (1988)
Mander et al. [30] derived a model for confinement of concrete from experimental values of 17 steel spiral reinforced concrete cylinders with varying ratios of reinforcement. The following relation for strength of confined concrete was proposed:

\[ f'_{cc} = f'_{co} \left( -1.254 + 2.254 \sqrt{1 + 7.94 \frac{f_{le}}{f_{co}} - 2 \frac{f_{le}}{f_{co}}} \right) \]  
Equation 3.8

where \( f_{le} \) is the effective lateral confining stress, which is affected by the steel reinforcement. For the purposes of this study, Mander et al. [30] suggested that \( f_{le} \) be assumed equal to \( f'_{l} \), the lateral confining stress, since steel reinforcement is not considered.

The longitudinal strain in the confined concrete was proposed as:

\[ \varepsilon_{cc} = \varepsilon_{co} \left[ 1 + 5 \left( \frac{f'_{cc}}{f'_{co}} - 1 \right) \right] \]  
Equation 3.9

3.2.4 Cusson and Paultre (1995)

Cusson and Paultre [9] developed a model based on tests conducted on 27 large scale square specimens made with high strength concrete with steel reinforcement. It was concluded that as the compressive strength of concrete increased, the effectiveness of the confining action and corresponding ductility decreased compared to normal strength concrete specimens. The model proposed was based on the 27 large scale specimens and 23 previously tested by the authors [9]. The regression analysis yielded the following expression for strength of confined concrete:
where $f_{le}$ is the effective lateral confining stress, which is affected by the steel reinforcement. As previously discussed, $f_{le}$ is assumed to equal $f_{c}$. It was also determined that the ultimate strain in the confined concrete using steel ties could be expressed as:

$$
\varepsilon_{cc} = \varepsilon_{co} + 0.21 \left( \frac{f_{le}}{f'_{co}} \right)^{1.7}
$$

Equation 3.11

### 3.2.5 Karbhari and Gao (1997)

Karbhari and Gao [20] developed two models to predict the effect of concrete confined by FRP. The first model, an empirical approach, modified Richart et al.’s [35] original model for concrete confined by steel in order to apply to FRP confined concrete. This approach yielded the following expressions for strength of confined concrete and ultimate strain:

$$
f'_{cc} = f'_{co} \left( 1 + 2.1 \left( \frac{f_{i}}{f'_{co}} \right)^{0.87} \right)
$$

Equation 3.12

$$
\varepsilon_{cc} = \varepsilon_{co} + 0.01 \left( \frac{f_{i}}{f'_{co}} \right)
$$

Equation 3.13

An alternate approach Karbhari and Gao [20] took was a simplistic composite analysis. This analysis generated the following expressions:
where \( E_f \) is the modulus of elasticity of the FRP in the hoop direction and \( E_c \) is the modulus of elasticity of the concrete and:

\[
\varepsilon_{cc} = 1 - \frac{1.004 \left[ 1 - \frac{f_{co}'}{E_{eff}} - 4.1 f_{co}' \nu_c \frac{2t_f}{D} \frac{E_f}{E_c E_{eff}} \right]}{(1 + \varepsilon_f)^2}
\]  
Equation 3.15

where \( \nu_c \) is Poisson’s ratio, \( \varepsilon_f \) is the strain in the FRP jacket and \( E_{eff} \) is the effective modulus of elasticity of the FRP in the hoop direction, which can be calculated using the following equation,

\[
E_{eff} = \frac{E_f A_f + E_c A_c}{A_f + A_c}
\]  
Equation 3.16

where \( A_f \) and \( A_c \) are the cross sectional areas of the FRP jacket and the concrete, respectively. \( \varepsilon_{co} \) was assumed to equal 0.002.

### 3.2.6 Miyauchi et al. (1998)

Miyauchi et al. [34] conducted compression tests on 10 concrete cylinders wrapped in Carbon FRP (CFRP). The specimens were comprised of two unconfined concrete strengths, \( f_{co} = 30 \) MPa and \( f_{co} = 50 \) MPa. Richart et al.’s [35] model was altered by adding an “effectiveness coefficient”, \( k_e \) with the following relationship:

\[
f_{cc}' = f_{co}' + 4.1 k_e f_f
\]  
Equation 3.17
Through calibration from the experimental data obtained, \( k_e \) was found to equal 0.85. Substituting \( k_e \) into Equation 3.17 yielded:

\[
f'_c = f'_c + 3.485 f_i \quad \text{Equation 3.18}
\]

Using the same set of experimental data, two models were derived for ultimate strain, dependent on the unconfined concrete strength, \( f'_{co} \).

\[
\varepsilon_c = \varepsilon_{co} + 10.6 \left( \frac{f_i}{f'_{co}} \right)^{0.373} \quad \text{Equation 3.19}
\]

for \( f'_{co} = 30 \) MPa and:

\[
\varepsilon_c = \varepsilon_{co} + 10.5 \left( \frac{f_i}{f'_{co}} \right)^{0.525} \quad \text{Equation 3.20}
\]

for \( f'_{co} = 50 \) MPa.

The authors provided no suggestions for situations of unconfined concrete strengths other than 30 MPa or 50 MPa.

### 3.2.7 Kono et al. (1998)

Kono et al.’s [21] models differ from most confinement models because they linearly relate the strengthening ratio, \( \frac{f'_c}{f'_{co}} \), directly to the confining pressure, \( f_i \). Most other models relate \( \frac{f'_c}{f'_{co}} \) to the confinement ratio, \( \frac{f_i}{f'_{co}} \). The authors performed a regression analysis on the results from the tests conducted to obtain the following expression for confined concrete strength:
Likewise, for the ultimate strain at failure, the authors linearly relate the strain ratio, $\frac{\varepsilon_{cc}}{\varepsilon_{co}}$ to $f_i$, whereas, other models relate $\frac{\varepsilon_{cc}}{\varepsilon_{co}}$ to the strengthening ratio, $\frac{f_i}{f_{co}'}$. The regression analysis yielded the following for ultimate strain:

$$\varepsilon_{cc} = \varepsilon_{co} + 0.28 \varepsilon_{co} f_i$$  

Equation 3.22

### 3.2.8 Samaan et al. (1998)

Samaan et al. [39] performed compression tests on 30 cylinders wrapped in FRP sheets of various thicknesses. Richart et al.’s [35] original model for steel confined concrete was used as a fundamental model. Based on the experimental data, the authors recommended a coefficient of confinement, $k_1 = 6.0 f_i^{-0.3}$. This yielded the following relationship:

$$f_{cc}' = f_{co}' + 6.0 f_i^{0.7}$$  

Equation 3.23

The ultimate strain at failure was determined from the bilinear nature of the stress-strain curve developed by the authors, where $E_2$ is the slope of the second portion of the curve. Ultimate strain could be calculated as:

$$\varepsilon_{cc} = \frac{(f_{cc}' - f_0)}{E_2}$$  

Equation 3.24
where \( f_0 = 0.872 f'_c + 0.371 f_t + 6.258 \) and \( E_2 = 245.61 f'_c^{0.2} + 1.3456 \frac{E_f t_f}{D} \).

### 3.2.9 Spoelstra and Monti (1999)

Spoelstra and Monti [45] modified Mander et al.’s [30] model to account for the increasing inward pressure caused by an FRP jacket. The resulting model for circular specimens wrapped with FRP used an iterative procedure. Spoelstra and Monti [45] derived an approximation of the iterative model by identifying key independent parameters, \( f_t, E_c, \) and \( \varepsilon_{com} \). Then a regression analysis was applied to incremental results from the iterative model. The resulting approximation assumed that the strain at unconfined peak stress, \( \varepsilon_{co} = 0.002 \). This assumption yielded:

\[
f'_c = f'_c \left[ 0.2 + 3.0 \sqrt{\frac{f_t}{f'_c}} \right]
\]

Equation 3.25

and for the ultimate strain:

\[
\varepsilon_{cc} = \varepsilon_{co} \left( 2 + 1.25 \frac{E_c}{f'_c} \sqrt{\frac{f_t}{f'_c}} \right)
\]

Equation 3.26

where \( \varepsilon_f \) is the ultimate strain in the FRP jacket.

### 3.2.10 Toutanji (1999)

Toutanji [48] conducted confinement test on 18 cylindrical specimens wrapped in CFRP and GFRP. A regression analysis was run on the experimental data obtained and resulted in the confining coefficient \( k \) to be the following:
By substituting $k_1$ into Richart et al.’s [35] original model, Equation 3.2, Toutanji [48] concluded that:

$$f'_{cc} = f'_{co} \left(1 + 3.5 \left( \frac{f_i}{f'_{co}} \right)^{0.85} \right)$$

Equation 3.28

For modeling of the ultimate strain in the confined concrete, Toutanji [48] suggested an expression which is derived from Richart et al.’s [35] model, but accounts for the dependent relationship on lateral strain in the composite, $\varepsilon_f$. Toutanji [48] expressed the constant, $k_2$ as:

$$k_2 = 310.57 \varepsilon_f + 1.90$$

Equation 3.29

When substituted into Richart et al.’s [35] model, the following expression was obtained:

$$\varepsilon_{cc} = \varepsilon_{co} \left[1 + \left(310.57 \varepsilon_f + 1.90 \left( \frac{f'_{cc}}{f'_{co}} - 1 \right) \right) \right]$$

Equation 3.30

where $\varepsilon_f$ ranges from the unconfined value of 0.002 to the ultimate value at failure.

**3.2.11 Saafi et al. (1999)**

Saafi et al. [38] proposed a model exactly the same as Toutanji’s [48] except that it was calibrated based on tests performed on FRP tube encased specimens instead of
FRP wrapped specimens. 18 concrete cylinders were tested with CFRP or GFRP tubes. Different coefficients than the FRP wrapped case were obtained because of the difference in bond strength between the FRP and concrete. The bond to the concrete cylinder with a wrapped specimen is stronger than that of a tube encased specimen. The following confining coefficients were obtained from the calibrations of the test results from the tube encased specimens:

$$k_1 = 2.2 \left( \frac{f_i}{f_i^{co}} \right)^{-0.16}$$  \hspace{1cm} \text{Equation 3.30}

which yielded the following for the ultimate strength of confined concrete:

$$f_{cc}' = f_{co}' \left[ 1 + 2.2 \left( \frac{f_i}{f_i^{co}} \right)^{0.84} \right]$$  \hspace{1cm} \text{Equation 3.31}

Similarly, the coefficient of confinement for the ultimate strain expression was determined to follow the equation:

$$k_2 = 537 \varepsilon_f + 2.6$$  \hspace{1cm} \text{Equation 3.32}

which yielded the following for the ultimate strain in the confined concrete:

$$\varepsilon_{cc} = \varepsilon_{co} \left[ 1 + \left( 537 \varepsilon_f + 2.60 \left( \frac{f_{cc}'}{f_{co}'} - 1 \right) \right) \right]$$  \hspace{1cm} \text{Equation 3.33}

3.2.12 Xiao and Wu (2000)
Xiao and Wu [53] tested 36 concrete cylinders wrapped in CFRP jackets. Richart et al.’s [35] model was used as a base relationship as follows:

\[ f''_{cc} = \alpha \cdot f'_{co} + k_1 f_l \]  
Equation 3.34

where in Richart et al.’s [35] model, \( \alpha = 1 \) and \( k_1 = 4.1 \). Based on the experimental data obtained, Xiao and Wu [53] suggested the average value of 1.1 for \( \alpha \) and the following expression for \( k_1 \):

\[ k_1 = 4.1 - 0.75 \frac{f'_{co}^2}{C_j} \]  
Equation 3.35

where \( C_j \) is the confinement modulus and could be expressed as:

\[ C_j = \frac{2tE_f}{D} \]  
Equation 3.36

By substituting into the original equation for strength of confined concrete from Richart et al. [35], the following relation was obtained:

\[ f''_{cc} = f'_{co} \left[ 1.1 + \left( 4.1 - 0.75 \left( \frac{f'_{co}^2 D}{2E_f t_f} \right) \right) \frac{f_l}{f'_{co}} \right] \]  
Equation 3.37

3.2.13 Lam and Teng (2002)

Lam and Teng [24] conducted over 200 tests on concrete cylinders to obtain strength data. The strength database included specimens of varying concrete strength, diameter, length to diameter ratios, and FRP type (CFRP, GFRP, and AFRP). Based on the strength database, Lam and Teng [24] recommended the following simple model for strength of confined concrete:
Equation 3.38

For modeling of the ultimate strain of confined concrete, Lam and Teng [24] compiled a strain database. The strain database was made up of 171 specimens. From this strain database, Lam and Teng [24] developed the following relation for the strain at ultimate stress:

\[
f'_{cc} = f'_{co} + 2.0 f_i
\]

Equation 3.39

where \( k \) is the strain enhancement coefficient, which depends on the type of FRP confinement. For CFRP, \( k \) was recommended as 15.

3.2.14 De Lorenzis and Tepfers (2003)

De Lorenzis and Tepfers [10] compiled a data set of about 180 experimental tests from a variety of authors. All specimens were concrete cylinders of varying size. The data set included specimens with CFRP, GFRP, and aramid FRP (AFRP) wrapped and tube encased cylinders of varying thicknesses. Using the collected data, De Lorenzis and Tepfers [10] proposed two new models for the ultimate strain in confined concrete. The models followed the form:

\[
\varepsilon_{cc} = \varepsilon_{co} \left[ 1 + c_1 \left( \frac{f_i}{f'_{co}} \right)^c_2 \frac{E}{\varepsilon_3} \right]
\]

Equation 3.40
where $c_1, c_2,$ and $c_3$ were chosen by minimizing the absolute error associated with the predicted values and the experimental results. $E_i$ is the confinement modulus and was calculated as:

$$E_i = \frac{2E_f t_f}{D} \quad \text{Equation 3.41}$$

For FRP wrapped specimens, the following expression was proposed:

$$\varepsilon_{cc} = \varepsilon\left[1 + 26.2\left(\frac{f_l}{f_{co}}\right)^{0.8}\left[\frac{E_f t_f}{D}\right]^{-0.148}\right] \quad \text{Equation 3.42}$$

and for FRP tube encased specimens the following expression was proposed:

$$\varepsilon_{cc} = \varepsilon\left[1 + 26.2\left(\frac{f_l}{f_{co}}\right)^{0.68}\left(\frac{E_f t_f}{D}\right)^{-0.127}\right] \quad \text{Equation 3.43}$$

### 3.2.15 Wu et al. (2003)

Wu et al. [52] compared data from over 200 specimens comprised of concrete cylinders confined with FRP wraps and tubes. The data set included many varying parameter including concrete strength, specimen dimensions, type of FRP (CFRP, GFRP, and AFRP), and tensile strength of FRP. Wu et al. [52] proposed a set of equations for the strength of confined concrete, $f_{cc}$, which is dependent on the type of jacket and the method used to determine the strength of the FRP, $f_f$.

For concrete confined by FRP sheets, where the strength of FRP is determined through tensile coupon tests, Wu et al. [52] suggested the following model:
\[ f'_{cc} = f'_{co} + 2.0 f_i \]  \hspace{1cm} \text{Equation 3.44}

For concrete confined by FRP sheets, where the strength of FRP was given by the manufacturer, the following relation was suggested:

\[ f'_{cc} = f'_{co} + 3.0 f_i \]  \hspace{1cm} \text{Equation 3.45}

and for concrete confined by FRP tubes, where the strength of FRP was determined through tensile coupon tests, Wu et al. [52] recommended the following relation:

\[ f'_{cc} = f'_{co} + 2.5 f_i \]  \hspace{1cm} \text{Equation 3.46}

To determine the strain in the confined concrete, Wu et al. [52] recommended a relation between the strain and Poisson’s ratio of the confined concrete:

\[ \varepsilon_{cc} = \frac{\varepsilon_f}{\nu_u} \]  \hspace{1cm} \text{Equation 3.47}

where \( \nu_u \) is Poisson’s ratio, which Wu et al. [52] suggested was dependent on the type of FRP and jacket (i.e. wrap or tube). For normal modulus CFRP, GFRP, and AFRP sheet confined concrete, Poisson’s ratio was expressed as:

\[ \nu_u = 0.56 \left( \frac{f_i}{f_{co}} \right)^{-0.66} \]  \hspace{1cm} \text{Equation 3.48}

For GFRP or CFRP tube confined concrete, Poisson’s ratio was:

\[ \nu_u = 0.31 \left( \frac{f_i}{f_{co}} \right)^{-0.44} \]
and for high modulus FRP, Poisson’s ratio was described as:

$$\nu_u = 0.56k_f \left( \frac{f_i}{f_{co}} \right)^{0.66}$$  \hspace{1cm} \text{Equation 3.50}

where $k_f$ is the influence coefficient for high modulus FRP and is equal to 1.0, when $E_f \leq 250$ GPa and $k_f = \sqrt{\frac{250}{E_f}}$ when $E_f > 250$ GPa.

\section*{3.2.16 Xiao and Wu (2003)}

Xiao and Wu [54] analyzed the results from 243 experimental specimens that were comprised of nine different types of FRP confinement, including CFRP and GFRP wrapped and tube encased specimens of varying thicknesses and unconfined concrete strengths. The model proposed is the same structure as previously proposed by Xiao and Wu [53]. The new model has more accurately calibrated constants based on the increase database of experimental specimens. Richart et al.’s [35] model was used again as a base relationship as follows:

$$f'_{cc} = \alpha \cdot f'_{co} + k_i f_i$$  \hspace{1cm} \text{Equation 3.51}

where in Richart et al.’s [35] model, $\alpha = 1$ and $k_i = 4.1$. Based on the experimental data obtained, Xiao and Wu [54] suggest the average value of 1.1 for $\alpha$ and the following expression for $k_i$:

$$k_i = 4.1 - 0.45 \frac{f_{c,4}}{C_j}$$  \hspace{1cm} \text{Equation 3.52}
This resulted in the following equation for strength of confined concrete:

\[
f'_{cc} = f'_{co} \left[ 1 + 1.1 \left( 4.1 - 0.45 \left( \frac{f'_{co}^2 D}{2E_f f_f} \right)^{1.4} \right) \frac{f_i}{f'_{co}} \right]
\]

Equation 3.53

3.2.17 Bisby et al. (2005)

Bisby et al. [5] analyzed several existing models based on an experimental data set of approximately 200 specimens from 20 different authors. The data set contained all three types of FRP (CFRP, GFRP, and AFRP). Specimens varied in size and concrete strength. Three models for strength of confined concrete were suggested based on regression analysis of the existing data sets. The three models express the coefficient of confinement, \( k_1 \), as either a constant, an exponential function of the confining stress ratio, \( \frac{f_i}{f'_{co}} \), or an exponential function of the ultimate confining stress, \( f_i \). The three proposed models are as follows:

\[
f'_{cc} = f'_{co} \left[ 1 + 2.425 \frac{f_i}{f'_{co}} \right]
\]

Equation 3.54

\[
f'_{cc} = f'_{co} \left[ 1 + 2.217 \left( \frac{f_i}{f'_{co}} \right)^{0.911} \right]
\]

Equation 3.55

\[
f'_{cc} = f'_{co} + 3.587 f_i^{0.840}
\]

Equation 3.56

Bisby et al. [5] recommend that all three models accurately predict the confining effect of FRP jackets. To model the ultimate strain of FRP confined concrete, Bisby et al. [5] recommend a model that is dependent on the type of FRP used:
\[ \varepsilon_{cc} = \varepsilon_{co} + k_2 \left( \frac{f_i}{f_{co}} \right) \]  

Equation 3.57

where \( k_2 = 0.0240, 0.0137, \) or \( 0.0536 \) for CFRP, GFRP, or AFRP, respectively.

### 3.2.18 Guralnick and Gunawan (2006)

Guralnick and Gunawan [14] developed a model for strength of confined concrete analytically by modifying Mohr’s strength theory. From previous tests conducted by the authors [14], it was determined that FRP confined concrete, which is classified as passive confinement was of the order of 2 for the Mohr’s strength envelope. By analyzing Mohr’s strength envelope circles at \( n = 2 \), Guralnick and Gunawan [14] developed an expression for \( f_{cc}' \) as follows:

\[ f_{cc}' = f_{co}' \left[ 0.616 + \frac{f_i}{f_{tco}} + 1.57 \left( \frac{f_i}{f_{tco}} + 0.06 \right)^{0.5} \right] \]  

Equation 3.58

The above model assumed the uniaxial tension of concrete, \( f_i' \approx 0.06 f_{co}' \) for a range of concrete strength of 3000 psi to 8000 psi.

### 3.2.19 Youssef et al. (2007)

Youssef et al. [55] performed tests on 87 large scale specimens (16 inch by 32 inch) and 30 standard sized specimens (6 inch by 12 inch) with CFRP and GFRP jackets. Based on 63 specimens for circular columns, Youssef et al. [55] calibrated an equation for confinement as follows:
The model for ultimate strain was calibrated as:

\[
\varepsilon_{cc} = 0.003368 + 0.259 \left( \frac{f_t}{f_{co}'} \right) \left( \frac{f_f}{E_f} \right)^{0.5}
\]  

Equation 3.60

3.2.20 Girgin (unpublished)

Girgin [13] assembled a wide range of experimental data from multiple sources. Data associated with lower levels of confinement, such as specimens wrapped in only one layer of FRP was disregarded. This yielded a set of 102 data points. Girgin [13] first evaluated the data with regards to Richart et al.’s [35] original model for strength of confined concrete, which was based on the Mohr-Coulomb failure criterion. Girgin [13] proposed the following expression for the confinement coefficient, \( k \):

\[
k = 2.109 \left( \frac{f_t}{f_{co}'} \right)^{-0.217}
\]  

Equation 3.61

This resulted in the following equation for ultimate strength:

\[
f_{cc}' = f_{co}' + 2.109 f_{co}' \left( \frac{f_t}{f_{co}'} \right)^{0.783}
\]  

Equation 3.62
Girgin [13] proposed an alternate model, which was based on the Hoek-Brown strength criteria. The Hoek-Brown failure for confined concrete could be expressed as:

\[ f_{cc}'' = f_i + s \cdot f_{co}''^2 + m \cdot f_{co}'' f_i \]  

Equation 3.63

Based on the experimental data set, the constants \( s \) and \( m \) were determined to equal 1 and 3.5, respectively for FRP wrapped concrete cylinders.

The following Table 3.1 summarizes the confinement models discussed.

3.3 Experimental Data

The experimental data set was comprised of over 300 specimen results previously conducted by several authors [6, 11, 15, 16, 17, 19, 20, 22, 23, 27, 28, 31, 33, 34, 38, 39, 44, 47, 49, 51, 53, 56]. The data set represented varying concrete strengths, specimen dimensions, jacket thicknesses, and types of FRP. Table 3.2 summarizes the range of data used. For all data sets, unless otherwise stated in the study, the elastic modulus of concrete, \( E \) is assumed to equal \( 4700 \sqrt{f_{c}'} \), where \( f_{c}' \) is the compressive strength of unconfined concrete in MPa.

3.4 Strength Evaluation

Figures 3.2 through 3.5 show the experimental data versus the predicted data from each strength model considered. The straight line represents perfect agreement between predicted and experimental strengths. Any data points that fall below this line are considered conservative (i.e. the predicted strength is less than the experimental strength). Likewise, any data points that fall above this line are considered non-conservative (i.e. the predicted strength is greater than the experimental strength).
Figure 3.2- Comparison of predictive strength models and experimental data.
Figure 3.3- Comparison of predictive strength models and experimental data.
Figure 3.4 - Comparison of predictive strength models and experimental data.
Figure 3.5- Comparison of predictive strength models and experimental data.
3.5 Strain Evaluation

Figures 3.6 through 3.9 show plots of the experimental data versus the predicted data from each strain model considered in this study. Similar to the confined strength graphs, the straight line represents perfect agreement between predicted and experimental strain. Any data points that fall below this line are considered conservative (i.e. the predicted strain is less than the experimental strain). Likewise, any data points that fall above this line are considered non-conservative (i.e. the predicted strain is greater than the experimental strain).
Figure 3.6- Comparison of predictive strain models and experimental data.

3.6 Proposed Model

Using the experimental data set, a regression analysis was performed to create a proposed model. The regression analysis yielded the following models for confined concrete strength and the corresponding ultimate strain:

\[
f'_{cc} = f'_{co} \cdot \left[ -0.503 \left( \frac{f'}{f'_{co}} \right)^2 + 2.7798 \frac{f'}{f'_{co}} + 0.9469 \right] \quad \text{Equation 3.64}
\]

\[
\varepsilon_{cc} = \varepsilon_{co} \cdot \left[ 1.0427 \left( \frac{f'_{cc}}{f'_{co}} \right)^2 - 1.1181 \frac{f'_{cc}}{f'_{co}} + 6.1949 \right] \quad \text{Equation 3.65}
\]

where \( f' \), \( f'_{co} \) and \( f'_{cc} \) are in MPa.

The above models for confined concrete strength and ultimate strain have a coefficient of correlation value, R-squared of 0.7449 and 0.5701, respectively. Figures 3.10 and 3.11 depict the predicted values of the proposed model versus the experimental data.
Figure 3.10- Comparison of proposed strength model and experimental data.

Figure 3.11- Comparison of proposed strength model and experimental data.
3.7 Discussion

Each model was evaluated using the root mean squared error (RMSE), as well as the coefficient of variance ($R^2$). Table 3.3 shows the rankings of the confined concrete strength models based on the lowest RMSE values. Similarly, Table 3.4 shows the rankings of the confined concrete strain models based on the lowest RMSE values. The strength model analysis was based on 311 data points and the strain model was based on 149 points.

Table 3.3- Ranking of strength models based on RMSE values.

The results show that the proposed model, Girgin’s Hoek-Brown model [13], and Karbhari and Gao’s [20] empirical model yield the best results for strength of confined concrete. Likewise, the proposed model, Mander et al.’s [30], and Miyauchi et al.’s [34] model most accurately predict the corresponding strain.

### 3.8 Conclusion

Several confinement models were evaluated and compared with a proposed model, which was developed using a regression analysis on the experimental data set. When evaluated, it was shown that the most accurate models for confined concrete
strength were the proposed model, Girgin’s Hoek-Brown model [13], and Karbhari and Gao’s [20] empirical model. Likewise for ultimate strain, the most accurate models were the proposed model, Mander et al.’s [30], and Miyauchi et al.’s [34] model most accurately predict the corresponding strain. However, the strain models in general are much less accurate than the strength models.
Chapter 4

Design Models

4.1 Introduction

There is currently no universally accepted design code for the seismic retrofit of concrete columns using FRP jackets. This chapter will review several design approaches commonly used in design for seismic retrofit and then compare the resulting jacket thicknesses recommended by each approach through a sample column design.

4.2 Background

A confined column has increased strength and ductility due to the passive restraint provided by the jacket, which restricts the lateral dilation of the column. The jacket provides a confining pressure on the concrete column, which suppresses micro-cracking and dilation of the concrete. Circular columns have the most efficient section for retrofitting; therefore, this paper will focus on circular columns only. For a circular column, the lateral confining pressure exerted on the concrete in the radial direction from the FRP jacket, $f_l$, can be evaluated using a free body diagram as shown in Figure 3.1, which results in the following relation:

$$
f_l = \frac{2t_f f_f}{D} = \frac{2t_f E_f \varepsilon_f}{D}
$$

Equation 4.1

where $f_f$ is the tensile strength of the FRP in the hoop direction, $t_f$ is the thickness of the FRP jacket, $D$ is the diameter of the confined concrete, $E_f$ is the modulus of elasticity of the FRP in the hoop direction and $\varepsilon_f$ is the strain in the FRP in the hoop direction.
Since FRP behaves elastically, the inward pressure due to a jacket increases continuously. In contrast, steel provides a constant lateral confining pressure. Therefore, confinement models and design approaches for steel jackets inaccurately model the elastic behavior of FRP.

The purpose of seismic retrofit is to increase the columns seismic response by increasing the columns ductility and axial strength. There are four major failure modes that FRP jackets can restrain: flexural, shear, lap slice and longitudinal bar buckling.

Flexural failure in the plastic hinge occurs near the column ends, where the behavior is that of a plastic hinge. Flexural failure can be observed through concrete spalling, failure of transverse steel reinforcement and buckling of longitudinal steel reinforcement, which cause deterioration of the plastic hinge. There is extensive deformation associated with this failure mode; therefore, it is considered a ductile and desirable failure mode as compared to shear failure. An FRP jacket provides confinement for the flexural failure mode, which increases the overall strength and ultimate strain and provides lateral support, which can hinder flexural failure.

Shear failure, in contrast to flexural failure, is a very brittle failure mode. It is; therefore, an extremely undesirable failure mode. Shear failure is characterized by diagonal shear cracks in the column and subsequent rupture of the transverse steel reinforcement. Shear failure is very prevalent in structures built prior to the 1971 San Fernando earthquake, which have insufficient transverse steel reinforcement corresponding to inadequate confinement. An FRP jacket can contribute to the overall shear strength of the column and thereby inhibit the failure.
Lap splice failure is a result of inadequate confinement in the splice in the longitudinal steel reinforcement. The splice region is confined to a small region near the column ends, where the starter bars from the footing are spliced with the column longitudinal reinforcement. The failure occurs because of dilation of the column, which results in debonding of the splice. Lap splice failure can be observed through concrete spalling, vertical cracks, rupture of transverse steel reinforcement and buckling of the longitudinal steel reinforcement. Similar to flexural failure, there is extensive deformation associated with lap splice failure; therefore, it is considered a ductile and desirable failure mode when compared to shear failure. An FRP jacket inhibits the lap splice failure mode through the application of confining pressure in the splice region, which creates a lateral clamping force and prevents debonding from occurring.

The last failure mode is buckling of the longitudinal steel reinforcement. This is considered to be a rare failure mode and is usually not considered by most design approaches.

### 4.3 Review of Design Models

There are a few existing design codes and guidelines for the seismic retrofit of concrete columns using FRP materials. Those codes and/or guidelines that will be reviewed include documents from the American Concrete Institute (ACI), California Department of Transportation (Caltrans), Concrete Society, and the Intelligent Sensing for Innovative Structures (ISIS) Canada Network of Center of Excellence. In addition to the official documents in place, there are a number of other approaches put forth. To contrast these approaches, an approach by Seible et al. [43] will be reviewed.
4.3.1 ACI 440.2R-02 (2002)

The ACI 440.2R-02 [1] guideline utilizes the confinement model originally proposed by Mander et al. [30] derived for steel hoop reinforcement. The confinement model from Mander et al. [30] is slightly modified to account for the linearly elastic behavior of FRP. The confinement model predicts the confined strength of concrete, \( f'_{cc} \) through the following relation:

\[
f'_{cc} = f'_{co} \left[ 2.25 \sqrt{1 + 7.9 \frac{f_i}{f'_{co}} - 2 \frac{f_i}{f'_{co}} - 1.25} \right]
\]

Equation 4.2

where \( f'_{co} \) is the unconfined concrete strength and \( f_i \) is the confining pressure, which is defined as:

\[
f_i = k_s \rho_f \varepsilon_f E_f
\]

Equation 4.3

where \( k_s \) is the efficiency coefficient, which depends on the column geometry. For a circular column \( k_s = 1.0 \). \( \varepsilon_f \) is defined as the lesser of 0.004 or 0.75 \( \varepsilon_{fu} \), where \( \varepsilon_{fu} \) is the ultimate strain in the FRP. This strain limit was chosen to avoid loss of interlock in the concrete aggregate and was determined through the study of experimental data. However, the limiting strain was determined from pure axial tests and is; therefore, an approximation for combined axial and bending situations induced by seismic forces. \( \rho_f \) is the FRP volumetric ratio and is equal to:

\[
\rho_f = \frac{4t_f}{D}
\]

Equation 4.4
The increased axial load carrying capacity of a strengthened column can be expressed as:

\[ \phi P_n = k_e \phi [0.85 \psi_f f'_{cc} (A_g - A_{st}) + f_y A_{st}] \]  

Equation 4.5

where \( k_e \) is the resistance factor ( = 0.85 for spiral reinforced columns and 0.8 for tie reinforced columns), \( P_n \) is the nominal axial load carrying capacity, \( \phi \) is the strength reduction factor and equal to 0.75, \( \psi_f \) is an additional reduction coefficient for FRP wrapped columns, which is equal to 0.95, \( A_{st} \) is the longitudinal steel area and \( f_y \) is the steel yield strength.

The above equation only considers the axial increase in strength. For retrofit in seismic areas, ACI 440 [1] suggests using Mander et al. [30] model for the confined strain, \( \varepsilon_{cc} \):

\[ \varepsilon_{cc} = \frac{1.71(5f'_{cc} - 4f'_{co})}{E_c} \]  

Equation 4.6

where \( E_c \) is the elastic modulus of the concrete. ACI 440 [1] suggests that the design should be developed to have sufficient strains associated with the desired displacement demands.

4.3.2 Caltrans Memo 20-4 (2000)
Caltrans Memo 20-4 [5] is specifically aimed at preventing flexural failure. Caltrans Memo 20-4 [5] recommends the use of a target confining stress, $f_i$, of 2,068 kPa (300 psi) and radial dilating strain, $\varepsilon_{cc}$, of 0.004 inside the plastic hinge zone. These limiting values were determined experimentally at a corresponding displacement ductility, $\mu$, of 6. For regions outside the plastic hinge zone, Caltrans Memo 20-4 [5] recommends $f_i = 1,034$ kPa (150 psi) and $\varepsilon_{cc} = 0.004$. The thickness can be calculated using the following equation, which was derived from equilibrium expression from Figure 4.1:

$$2t_f E_f \varepsilon_{cc} = f_i D$$  \hspace{1cm} \text{Equation 4.7}

where $E_f$ is the elastic modulus of FRP multiplied by a reduction safety factor of 0.9. This approach is solely based on target confinement pressures and does not specifically account for the various failure modes possible.

### 4.3.3 Concrete Society Technical Report No. 55 (2004)

The Concrete Society Technical Report No. 55 [8], similar to the Caltrans Memo 20-4 [5], sets a target confining pressure. The design sets a minimum value of 0.183 mm$^2$/N for the following ratio, which was determined through experimental testing:

$$\frac{2t_f E_f}{D(f'_{co})^2} > 0.183 \frac{mm^2}{N}$$  \hspace{1cm} \text{Equation 4.8}

### 4.3.4 ISIS Canada Network of Centers of Excellence (2001)
ISIS Canada [18] set up design guidelines based on limiting levels of confining pressure. According to this approach, the confined strength of concrete can be found through:

\[ f'_{cc} = f'_{co} (1 + \alpha_{pc} w_w) \quad \text{Equation 4.9} \]

where \( \alpha_{pc} \) is a performance coefficient that depends on column geometry and is equal to 1.0 for circular columns and \( w_w \) is the volumetric strength ratio, which is expressed by the following relation:

\[ w_w = \frac{2 f_i}{\phi_c f'_{co}} \quad \text{Equation 4.10} \]

where \( \phi_c \) is the concrete resistance reduction factor and is equal to 0.6 and the confining pressure \( f_i \) is determined from:

\[ f_i = \frac{2 N_b \phi_{frp} E_f \varepsilon_f t_f}{D} \quad \text{Equation 4.11} \]

where \( N_b \) is the number of FRP layers, \( \phi_{frp} \) is a reduction factor for FRP, which is equal to 0.75.

To ensure a certain level of ductility a minimum amount of confining pressure imposed is equal to 4 MPa. This minimum confining pressure is four times the target pressure of 1 MPa for Caltrans Memo 20-4 [5]. Also a maximum level of confining pressure is imposed to limit amount of axial strains.
The approach proposed by Seible et al. [43] differs from most of the aforementioned documents because it considers each failure mode separately and calculates a design thickness associated with each of the failure modes. For shear failure, the required thickness is calculated as follows:

\[ t_j = \frac{\frac{V_a}{\phi_Y} - (V_c + V_s + V_p)}{\frac{\pi}{2} \cdot 0.004 E_Y D} \]  

Equation 4.13

where \( V_a \) is the column shear demand based on full flexural over-strength in the potential plastic hinge region, \( \phi_Y \) is the shear capacity reduction factor, assumed to be 0.85, \( V_c \) is the shear capacity contribution from concrete, \( V_s \) is the shear capacity contribution from horizontal steel reinforcement and \( V_p \) is the shear capacity contribution from axial load. The shear demand, \( V_o \) is calculated from the as built moment capacity, \( M_{yi} \). Therefore, the shear demand is expressed as:

\[ V_o = \frac{1.5 M_{yi}}{H} \]  

Equation 4.14

where \( H \) is the height of the column.
The shear contributions from concrete can be calculated through the following expressions:

\[ V_c = k \sqrt{f_{co}' A_e} \]  

Equation 4.15

where \( k \) is 0.5 inside the plastic hinge and 3.0 outside the plastic hinge and \( A_e \) is the effective area, which is equal to 0.8 times the gross area of the column. However, for damaged columns the contribution due to concrete should be neglected, since cracks large enough to lose aggregate interlock are most likely present.

The shear contribution from the steel hoop reinforcement is calculated from:

\[ V_s = \frac{\pi}{2} A_h f_y D' \cot(\theta) \]  

Equation 4.16

where \( A_h \) is the area of hoop steel reinforcement and \( \theta \) is the angle of shear crack, which can conservatively be assumed as 45°, \( s \) is the spacing between steel hoops and \( D' \) is the effective diameter, which is equal to the overall diameter, \( D \) minus twice the concrete cover, \( cc \) minus the diameter of a steel hoop bar, \( d_h \).

The shear contribution from the axial load is determined by:

\[ V_p = \frac{P(D - c)}{H} \]  

Equation 4.17

where \( P \) is the axial load applied and \( c \) is the neutral axis depth.

The shear thickness is applied over the shear reinforcement length, \( L_v \) from either end of the column, where \( L_v \) is equal to 1.5 times the diameter of the column, \( D \).
For flexural hinge failure mode, the thickness in the flexural hinge region is calculated as follows:

\[
 t_j = 0.09 \frac{D(e_{cu} - 0.004)f_{cc}'}{\phi f_f \epsilon_f} \tag{4.18}
\]

where \( \phi_f \) is the flexural capacity reduction factor, assumed as 0.9, \( f_{cc}' \) is conservatively assumed as 1.5 \( f_{co} \) and \( e_{cu} \) is the ultimate concrete strain that depends on the level of confinement and is calculated as:

\[
 e_{cu} = 0.004 + \frac{2.8 \rho_j f_f \epsilon_f}{f_{cc}'} \tag{4.19}
\]

where \( \rho_j \) is the volumetric jacket reinforcement ratio, \( e_{cu} \) can be obtained from:

\[
 e_{cu} = \Phi u c_u \tag{4.20}
\]

where \( c_u \) is the neutral axis depth and \( \Phi_u \) is the ultimate section curvature can be obtained from the ductility factor equation:

\[
 \mu_{\Delta} = 1 + 3 \left( \frac{\Phi_u - 1}{\Phi_y} \right) \frac{L_p}{L} \left( 1 - 0.5 \frac{L_p}{L} \right) \tag{4.21}
\]

where \( L_p \) is the plastic hinge length and determined from:

\[
 L_p = 0.08L + 0.022 f_y d_b \tag{4.22}
\]
and $\Phi_y = $ section yield curvature.

The thickness required for the flexural reinforcement jacket is applied over the flexural plastic hinge region, where $L_{c1}$ is the primary flexural hinge region and is equal to the greater of 0.5D or L/8, and $L_{c2}$ is the secondary flexural hinge region and is equal to the greater of 0.5D or L/8. The secondary flexural hinge region has $t/2$ thickness.

The lap splice failure mode is prevented through applying a thickness in the lap-splice region of:

$$t_j = 500 \frac{D(f_i - f_h)}{E_f}$$  \hspace{1cm} \text{Equation 4.23}

where $f_h$ is the horizontal stress provided by the existing hoop reinforcement at a strain of 0.1% and is calculated through the following relation:

$$f_h = \frac{0.002A_pE_s}{D \cdot s}$$  \hspace{1cm} \text{Equation 4.24}

and $f_i$ is the lateral clamping pressure, which can be found from:

$$f_i = \frac{A_s f_y}{\left[ \frac{p}{2n} + 2(d_h + cc) \right] L_s}$$  \hspace{1cm} \text{Equation 4.25}
where \( p \) is the perimeter line in the column cross section along the lap-spliced bar locations, \( n \) is the number of spliced bars along \( p \), \( A_i \) is the area of one main column reinforcing bar, \( cc \) is the concrete cover to the main column reinforcement and \( d_b \) is the diameter of main column reinforcement bars. The length to which the lap splice reinforcement is applied, \( L_s \), must be greater than the lap length itself.

### 4.4 Design Example

Two sample columns were chosen based on existing testing data from Sieble and Innamorato [41] and Seible et al. [40]. Seible and Innamorato [41] report on an investigation wherein a reinforced concrete column, which was deficient in shear was wrapped with carbon fiber FRP and then subjected to the given loads. Similarly, Sieble et al. [40] reported on a flexural deficient column with a lap splice, which was wrapped with a carbon fiber FRP jacket. Table 4.1 shows the properties and loads for the sample shear column and Table 4.2 shows the properties and loads for the sample flexural column.

</table>
Using the properties from the shear and flexural examples, design thicknesses were calculated using each approach described above. In addition, the approaches that included the confined strength of concrete or the confined strain of concrete within the design calculations were modified to include the two best models from Chapter 2. The best two models for the confined strength of concrete were determined in Chapter 2 as the proposed model and Girgin [13]. The two best models for the associated strain were the proposed model and Mander et al. [30]. Only two design models incorporated the confined strength of concrete and/or the associated strain into the design procedure. ACI-440.2R [1] used both the confined strength and the associated strain; therefore, there were a total of ten modified approaches using combinations of the various confinement models. Figure 4.1 shows the different design approaches that were considered.
Figure 4.1- Variations of ACI 440.2R [1] design code considered.
Similarly, the Seible et al. [43] design approach incorporated the confined strength of concrete into the flexural strengthening calculations; therefore, alternate design thicknesses were determined using each of the different strength models considered. Figure 4.2 shows the alternate approaches considered for the Seible et al. [43] design calculations.

![Diagram of Seible et al. Variations](image)

**Figure 4.2- Variations of Seible et al. [43] considered.**

Each design approach was analyzed using the sample column and the theoretical design jacket thickness required was determined. The design thickness was determined for a ductility of 8 and 10. Table 4.3 shows the resulting required thicknesses for each design approach for the shear column example. The table also shows any modifications made to the design approach through the confined strength model or the confined strain model. Similarly, Table 4.4 shows the thicknesses and variations for the flexural column example. Individual calculations for each approach are detailed in Appendix A.
Table 4.3- Summary of required design thicknesses for shear deficient column.

4.5 Discussion

As can be seen from Tables 4.3 and 4.4, there is a wide range of recommended design thicknesses from the various approaches. It is noted that these sample columns were retrofitted and tested to determine the level of ductility achievable and therefore an experimental data set can be used for assessment of the results.

For the shear column, experimental tests conducted by Seible and Innamorato [41] used a carbon fiber jacket which consisted of 1.524 mm for the first 305 mm, 1.041 mm for the next 914 mm and 0.61 mm for the middle 610 mm of the specimen. These design thicknesses correspond to the Seible et al. [43] design approaches with a desired ductility of 8, but were slightly knocked down to account for conservativeness. Table 4.5 shows the percent error of each approach when comparing the design models for a desired ductility of 10 and the experimental thickness, which was proven to provide a ductility of 10 from the tests.

</table>
The tests concluded that the carbon FRP wraps significantly increased the ductility of the column from 3 to well over the desired target ductility of 8 to a level around 10. This suggests that even the slightly knocked down design values used for the test were significantly conservative as well. Therefore, a less conservative design approach could be used.

It can be seen that the ACI 440.2R [1] and ISIS Canada [18] design approaches are extremely conservative and yield design thicknesses approximately twice than that from tested specimen. Therefore, these two approaches will be discarded from further consideration in this study. In contrast, the Concrete Society Technical Report No. 55 [8] yields much smaller design thicknesses than the tested specimen, approximately half the value. While this may be a viable design approach that could eliminate the conservatism in the current design approaches, more research would be needed to instill confidence in this method for design.

Alternatively, there is the Caltrans Memo 20-4 [5], which yields design thicknesses slightly less that used for the specimen. The suggested design thicknesses from Caltrans Memo 20-4 [5] are almost exactly the same as the actual thicknesses used in the Seible and Innamorato [41] tests, which yielded very good, conservative results. Combined with the relative ease of this approach in comparison with Seible et al. [43] makes Caltrans Memo 20-4 [5] a very practical design approach.

However, the Caltrans Memo 20-4 [5] does not consider the desired level of ductility in the design. Therefore, the design thickness may not be appropriate for ductility levels lower than 10. Figure 4.3 shows the required design thicknesses for

![Graph](image)

Figure 4.3- Comparison of models based on ductility.

It can be seen from Figure 4.3 that Caltrans Memo 20-4 [5] requires a constant thickness regardless of the desired ductility level; whereas, in the Seible et al. [43] approach the thickness decreases significantly as the desired ductility decreases. The Caltrans Memo 20-4 [5] approach was verified through the previously discussed experimental tests at high desired ductilities. Therefore, for design purposes for a shear column Caltrans Memo 20-4 [5] should be used when the desired ductility is above 6.5 to minimize material used and the Seible et al. [43] approach should be used for ductility level below 6.5. However, since the Seible et al. [43] is very complex and
mathematically in depth, it is possible based on Figure 4.4 to use a reduction factor along with the Caltrans Memo 20-4 [5] approach when the desired ductility is below 6.5. If the Seible et al. [43] is approximated as linear with ductility, then to calculate the required thickness when the desired ductility is less than 6.5 the following expression could be used derived from the Caltrans Memo 20-4 [5] approach:

\[
    t_f = \frac{f_i D}{2E_f \varepsilon_{cc}} - \left( \frac{f_i D}{2E_f \varepsilon_{cc}} - 0.4925 \mu - 1.725 \right)
\]

where \( f_i = 2,068 \text{ kPa (300 psi)} \) and radial dilating strain, \( \varepsilon_{cc} \), of 0.004 inside the plastic hinge zone and \( f_i = 1,034 \text{ kPa (150 psi)} \) and \( \varepsilon_{cc} = 0.004 \) outside the plastic hinge zone. When the desired ductility is greater than 6.5, the regular Caltrans Memo 20-4 [5] could be used.

For the flexural column, experimental tests conducted by Seible et al. [40] used a carbon fiber jacket, which consisted of 5.08 mm for the first 457 mm, 2.54 mm for the next 457 mm of the specimen. These design thicknesses correspond to the Seible et al. [43] design approaches with a desired ductility of 8. Table 4.6 shows the percent error of each approach when comparing the design models for a desired ductility of 10 and the experimental thickness, which is proven to provide a ductility of 10 from the tests.

The tests concluded that the carbon FRP wraps significantly increased the ductility of the column from 3 to well over the desired target ductility of 8 to a level around 10. This suggests that even the slightly knocked down design values used for the test were significantly conservative as well. Therefore, a less conservative design approach could be used.

It can be seen that the ACI 440.2R [1] and the Concrete Society Technical Report No. 55 [8] and the variations of Seible et al. [43] design approaches are extremely conservative and yield design thicknesses much thicker than the tested specimen. In contrast, the Caltrans Memo 20-4 [5] and the ISIS Canada [18] approaches yield much smaller design thicknesses than that used in the tested specimen. This may be a viable design approach that could eliminate the conservatism in the current design approaches, more research would be needed to instill confidence on this method for design.

The two models that produce design thicknesses with the least amount of error are the ACI 440.2R [1] approach modified using the proposed strength of confined concrete and the proposed confined strain models and the Seible et al. [43] design approach. The modified ACI 440.2R [1] approach yields a conservative design thickness; whereas, the Seible et al. [43] approach is very slightly non-conservative in the secondary plastic hinge region. However, the test specimen thickness was determined to be conservative itself, so a very slightly non-conservative design approach may be acceptable in this context.

4.6 Conclusion
It can be seen from the example design problems above that there are significant
differences in the various design approaches. The design thicknesses ranged from 0.534
mm to 7.47 mm for the shear column example and from 0.534 mm to 48.41 mm for the
flexural column example. This proves the need for more research in the design code
approaches used and the need to unify and find a universally accepted approach. One
major problem with the design guidelines today is the over conservatism of most codes
and guideline due to the lack of knowledge and confidence with the current design codes
and guidelines. With more research, that confidence will go up and the overall
conservatism will decrease, which will lead to more efficient designs and a decrease in
overall cost of material, which will make FRP jackets even more desirable than the steel
alternative.

For this research, it was determined that the Caltrans Memo 20-4 [5] design
approach is the most practical model for a shear column with a desired ductility greater
than 6.5, due to its slight conservatism and simplicity. Simplicity of the design
calculations will be very important for this application in order to help speed and ease the
process of emergency repair. However, when the desired ductility is less than 6.5, the
Caltrans Memo 20-4 [5] is much more conservative, since it does not account for the
desired ductility in the design. Therefore, for shear column with a desired ductility below
6.5, it is more practical to use the Seible et al. [43] design approach. However, the
Caltrans Memo 20-4 [5] could be used at desired levels of ductility less than 6.5 with a
reduction factor using Equation 4.26. This approach allows one to use the more simple
approach at lower desired ductilities without sacrificing the level of conservatism.
A shear column or a short column is defined by the ACI 318-08 [2] in section 10.13.2 of the building code from the ratio of the unbraced length, \( l \) and the radius of gyration, \( r \). The code states that the slenderness effect may be neglected is the ratio of unbraced length to the radius of gyration, also known as the slenderness ratio, \( \frac{l}{r} \) is less than 22, where the radius of gyration is equal to \( \sqrt{\frac{I}{A}} \), where \( I \) is the moment of inertia and \( A \) is the cross sectional area. For a circular column the slenderness ratio is equal to \( \frac{4H}{D} \), where \( H \) is the height of the column and \( D \) is the diameter.

Similarly, for flexural columns it was determined that the Seible et al. [43] approach is the most practical for design. These models are only validated for carbon/epoxy FRP jackets. There would need to be additional research conducted to validate these aspects for other FRP systems.
Chapter 5

Strain Based Design

5.1 Introduction

The design models discussed in Chapter 4 can be used for repair of damaged columns; however, it would be beneficial to have a more rapid, simple approach that can be implemented in the field in emergency situations.

This chapter will discuss an alternate design approach, which will determine a design thickness based on the amount of strain in the spiral hoop reinforcement or the longitudinal reinforcement, determined in Chapter 2, and the associated loss of axial capacity in the concrete column.

5.2 Axial Capacity Loss

As presented in Chapter 2, each damage state (DS-1 through DS-5) has a strain range associated with it for the spiral hoop reinforcement and the longitudinal reinforcement. Each strain value can be associated with an axial capacity from a sectional analysis. The axial capacity at a specific strain level can be compared to the original theoretical capacity of the column prior to damage, which can be determined using the ACI 318 [2] equations for axial capacity as follows:

\[ \phi P_n = 0.8\phi \left[ 0.85\left( f_c' A_g + f_{ecc}' A_{ec} \right) + f_y A_s \right] \quad \text{Equation 5.1} \]
where $\phi P_a$ is the axial capacity, $\phi$ is the reduction factor for the transverse reinforcement, which is equal to 0.75 for spiral hoops, $A_g$ is the gross cross sectional area of the column, $A_{ec}$ is the area confined by the transverse reinforcement, $f_y$ is the yield strength of the longitudinal reinforcement, $A_s$ is the area of longitudinal reinforcement and $f'_{ccs}$ is the confined strength of concrete due to the transverse reinforcement. The confined strength of concrete due to the transverse reinforcement $f'_{ccs}$ can be determined using Richart et al.’s [35] relation for steel spiral hoops:

$$f'_{ccs} = f'_{c} + 4.1 f_i$$  Equation 5.2

where $f_i$ is the confining pressure provided by the spiral hoops and is calculated as:

$$f_i = \frac{2 A_h f_{sy}}{d \cdot s}$$  Equation 5.3

where $A_h$ is the cross sectional area of the spiral hoop, $f_{sy}$ is the yield strength of the spiral hoop steel, $d$ is the diameter of the column that is confined by the hoops, which is equal to the gross column diameter, $D$ minus twice the concrete cover, $cc$ minus twice the diameter of the spiral hoop, $d_h$ and $s$ is the spacing of the spiral hoops.

The loss in axial capacity for each damage state is simply the axial capacity calculated from the as-built using Equation 5.1 minus the axial capacity from the sectional analysis at the given strain value for that damage state.

### 5.3 Design Approach

Using the loss of axial capacity at a given damage state, the required confined strength of the FRP jacket needed to restore the original axial capacity of the undamaged column can be determined. The confining effect of the FRP jacket can be added into the
expression for axial capacity, Equation 5.1. The new expression for axial capacity is expressed as:

$$\phi P_n = 0.8\phi[0.85(f'_c A_g + f'_{cc} A_{cc} + f'_{cc} A_g)]$$  \hspace{1cm} \text{Equation 5.4}$$

The effect of the longitudinal bars is neglected since they can show some level of yielding even at damage state DS-1. Since the loss of axial capacity is known, the required effect of the FRP jacket can be determined. Therefore, the required confined strength of concrete due to the FRP jacket, $f'_{cc}$ can be determined as:

$$f'_{cc} = \frac{\phi P_{no} - \phi P_{new}}{0.8\phi 0.85 A_g}$$  \hspace{1cm} \text{Equation 5.5}$$

where $\phi P_{no}$ is the initial axial capacity determined from Equation 5.1 and the as-built drawings and $\phi P_{new}$ is the reduced axial capacity for the given damage state from the sectional analysis and the associated strain level.

Once the required confined strength due to the FRP jacket is determined, a design thickness can be calculated using the Caltrans Memo 20-4 [5] approach along with Mander et al.’s [30] confined strength model or the confinement models in Chapter 3, so as to compare various approaches.

5.4 Design Example

A sample column was used to demonstrate how this approach can be implemented. Table 5.1 shows the properties of the sample column and the CFRP jacket used to repair the deficiency.

The sample column was classified as a DS-4 based on visual examination. The initial axial capacity was determined to equal 2722 kN using Equation 5.1. The associated strain, as determined in Chapter 2 for DS-4 is 0.0348 for the longitudinal reinforcement and 0.00167 for the transverse reinforcement. Using these strain levels, an axial capacity was determined from a sectional analysis using Response 2000 software program. The new axial capacity was 174.9 kN. Using Equation 5.5 the required confined strength due to the FRP jacket was determined to equal 68.36 MPa.

Three approaches were then evaluated using the Caltrans Memo 20-4 [5] approach along with Mander et al.’s [30] confined strength model and the two best strength models from Chapter 3, the proposed strength model and Girgin’s [13] strength model. The resulting design thicknesses were 5.0 mm, 2.81 mm and 5.67 mm using the Caltrans Memo 20-4 [5] approach, the proposed strength model and Girgin’s [13] strength model, respectively. Individual calculations for each approach are detailed in Appendix B. The Caltrans Memo 20-4 [5] and Girgin’s [13] strength model approaches are very conservative in comparison with the proposed strength model approach.
5.5 Discussion

The column described in the design example above was tested by Vosooghi and Saiidi [50]. The Caltrans Memo 20-4 [5] approach from Chapter 4 was used, not the modified approach described within this chapter. The design thickness was 2.03 mm. Vosooghi and Saiidi [50] concluded that repair design was effective in restoring strength and ductility to the damaged column. It was observed that the strength, ductility capacity and drift capacity were restored to at least that of the original column. It was also determined that 87% of the stiffness was restored.

When the column design that was tested is compared to the design thicknesses produced from the approaches discussed in this chapter, it is concluded that the proposed strength model approach is most accurate in determining design thickness. The Caltrans Memo 20-4 [5] approach and Girgin’s [13] strength model are much too conservative. The proposed strength model approach is slightly conservative for the DS-4 design. However, since the approach used by Vosooghi and Saiidi [50] is constant for all damage states and the proposed model approach design thickness decreases as the damage state decreases, the proposed strength model approach should be less conservative for lower damage state levels and is actually based on changed in damage rather that use of a “one-size-fits-all” approach. The proposed strength model can be simplified in terms of thickness as follows:

\[
t_f = \frac{1}{2} \left[ \frac{13899}{5030} \cdot f'_c - \frac{1}{5030} \cdot \left(240811270 \cdot f'_c - 5.03 \cdot 10^7 \cdot f''_c \cdot f'_c \right)^{1/2} \right] \cdot \frac{D}{f_f}
\]

Equation 5.6
5.6 Conclusion

A design approach for each damage state was derived using the strain levels expected for each damage state. The strain was related to a loss in axial capacity using sectional analysis, which was used to design an FRP jacket for repair.

Three design approaches were considered and compared. The Caltrans Memo 20-4 [5], the proposed strength model and Girgin’s [13] strength model were used to calculate a jacket thickness for an experimental column. It was determined that the proposed strength model is a more accurate design approach. This design approach provides a simple method to determine a jacket thickness based on the level of damage observed in the column.
Chapter 6

Decision Tree

6.1 Decision Tree

Figure 6.1 shows the final basis for the decision tree using the proposed strain based design discussed in Chapter 5. This decision tree will aide engineers in determining the level of damage to a column through visual inspection, determine whether repair using an FRP jacket is appropriate, and then design the FRP jacket if repair is appropriate.
Figure 6.1- Decision tree for emergency repair.
Chapter 7

Example

7.1 Example

The following example is a reinforced concrete column with a diameter of 305 mm. The step-by-step design example shows how to calculate the different design thicknesses for each damage state level.
Column Properties:

\[ D = 305 \text{mm} \]
\[ e_c = 19 \text{mm} \]
\[ A_e = 16 \cdot 71 \text{mm}^2 \]
\[ A_x = 1.136 \times 10^3 \text{mm}^2 \]
\[ d_h = 4.877 \text{mm} \]
\[ d_b = 0.192 \text{in} \]
\[ d_s = D - 2 \cdot e_c - 2 \cdot d_h \quad d_s = 257.246 \text{mm} \]
\[ f''_c = 34.48 \text{MPa} \]
\[ A_{th} = \frac{\pi \cdot (d_h)^2}{4} \quad A_{th} = 18.681 \text{mm}^2 \]
\[ A_{tb} = 0.029 \text{in}^2 \]
\[ E_p = 29000 \text{ksi} \]
\[ E_b = 1.599 \times 10^5 \text{MPa} \]
\[ e = 32\text{mm} \]
\[ f_{yh} = 413.685 \text{MPa} \]
\[ f_{yb} = 69 \text{ksi} \]
\[ f_{ys} = 468.43 \text{MPa} \]
\[ f_{ys} = 67.94 \text{ksi} \]

Composite Properties:

\[ f_c = 752 \text{MPa} \]
\[ f_y = 109.008 \text{ksi} \]
\[ E_c = 59360 \text{MPa} \]
\[ E_y = 8.609 \times 10^4 \text{ksi} \]

Confining Pressure Provided by Steel Hoops:

\[ f_{th} = \frac{2A_{th} \cdot f_{yh}}{d_b \cdot e} \]
\[ f_{th} = 272.319 \text{psi} \]
\[ f_1 = f_{th} \]
\[ f_1 = 1878 \text{MPa} \]

Initial Axial Capacity:

\[ f_{oes} = f_c + 4.11 f_1 \]
\[ f_{oes} = 42.178 \text{MPa} \]
\[ A_b = \frac{\pi \cdot D^2}{4} \]
\[ A_b = 7.306 \times 10^6 \text{mm}^2 \]
\[ A_{oc} = \frac{(d_b)^2 \cdot \pi}{4} \quad A_{oc} = 5.197 \times 10^6 \text{mm}^2 \]
\[ f_s = 0.75 \]

\[ \theta_{P_{100}} = 0.8 \cdot 0.85 \cdot f_b \left( f_c \cdot A_b + f_{oes} \cdot A_{oc} \right) + 0.8 \cdot f_b \cdot A_b \cdot f_{ys} \]
\[ \theta_{P_{100}} = 2.722 \times 10^3 \text{kN} \quad \text{Initial Axial Capacity} \]

Proposed Strength Model:

\[ f_{oc} = f_c \left[ 0.50 \left( \frac{2 \cdot f_c \cdot f_{ys}}{D \cdot f_c} \right)^2 + 7.798 \cdot \left( \frac{2 \cdot f_c \cdot f_{ys}}{D \cdot f_c} \right) + 0.9469 \right] \]
Figure 7.1- Axial capacity of column versus longitudinal strain from sectional analysis program, Response 2000 [4].
DS-1
New column capacity:
\[ \Phi_{P_{\text{new}}} = 689.2 \text{kN} \]
Required strength from jacket:
\[ \gamma_{cc} = \frac{\Phi_{P_{\text{new}}} - \Phi_{P_{\text{new}}}}{0.8 \cdot 0.85 \cdot \phi_{s} \Lambda_{b}} \]
\[ \gamma_{cc} = 54.557 \text{MPa} \]
Proposed Strength Model
\[ 54.557 = 34.48 \left[ -0.503 \left( \frac{2 \cdot 752 - 101}{305 - 34.48} \right)^{2} + 2.7798 \left( \frac{2 \cdot 752 - 101}{305 - 34.48} \right) + 0.9469 \right] \quad \text{solve,} \quad t_{f1} \rightarrow \left( \frac{1.67 \times 10^{4} \rho_{c} \times 2060}{3.6972 \times 10^{12}} \right) \]
\[ t_{f} = 1.67 \text{mm} \]
\[ t_{f} = 0.066 \text{in} \]

DS-2
New column capacity:
\[ \Phi_{P_{\text{new}}} = 338.7 \text{kN} \]
Required strength from jacket:
\[ \gamma_{cc} = \frac{\Phi_{P_{\text{new}}} - \Phi_{P_{\text{new}}}}{0.8 \cdot 0.85 \cdot \phi_{s} \Lambda_{b}} \]
\[ \gamma_{cc} = 63.963 \text{MPa} \]
Proposed Strength Model
\[ 63.963 = 34.48 \left[ -0.503 \left( \frac{2 \cdot 752 - 101}{305 - 34.48} \right)^{2} + 2.7798 \left( \frac{2 \cdot 752 - 101}{305 - 34.48} \right) + 0.9469 \right] \quad \text{solve,} \quad t_{f1} \rightarrow \left( \frac{2.4382 \times 10^{4} \rho_{c} \times 2060}{3.6204 \times 10^{12}} \right) \]
\[ t_{f} = 2.44 \text{mm} \]
\[ t_{f} = 0.096 \text{in} \]

DS-3
New column capacity:
\[ \Phi_{P_{\text{new}}} = 233.3 \text{kN} \]
Required strength from jacket:
\[ \gamma_{cc} = \frac{\Phi_{P_{\text{new}}} - \Phi_{P_{\text{new}}}}{0.8 \cdot 0.85 \cdot \phi_{s} \Lambda_{b}} \]
\[ \gamma_{cc} = 66.792 \text{MPa} \]
Proposed Strength Model
\[ 66.792 = 34.48 \left[ -0.503 \left( \frac{2 \cdot 752 - 101}{305 - 34.48} \right)^{2} + 2.7798 \left( \frac{2 \cdot 752 - 101}{305 - 34.48} \right) + 0.9469 \right] \quad \text{solve,} \quad t_{f1} \rightarrow \left( \frac{2.67 \times 10^{4} \rho_{c} \times 2060}{3.5966 \times 10^{12}} \right) \]
\[ t_{f} = 2.68 \text{mm} \]
\[ t_{f} = 0.106 \text{in} \]
It can be seen from this simple design example that the design thickness will increase as the damage state becomes more severe. The resulting design thicknesses are 1.67 mm, 2.44 mm, 2.68 mm and 2.81 mm for DS-1, DS-2, DS-3 and DS-4, respectively.
Chapter 8

Conclusions and Future Research

8.1 Conclusions

A basis for a decision tree was presented to help engineers quickly design a CFRP jacket for damaged reinforced concrete columns for emergency repair. The decision tree first determines a level of damage based on visual inspection of the damaged column. The damage states were classified into five levels, DS-1 through DS-5, based on the level of visual damage. Strain ranges for longitudinal and transverse reinforcement associated with each damage state level were determined. From these strain levels, it was determined that DS-1 would not require repair, unless one layer of jacket is desired for aesthetic reasons. It was also concluded that DS-5 would not be appropriate to repair using an FRP wet layup jacket, since the damage has penetrated into the concrete core and transverse reinforcement has yielded.

Modeling concrete confinement from an FRP jacket is considered because FRP does not behave like the traditional steel jackets, since they are perfectly elastic to failure. Therefore, several existing confinement models were analyzed and compared with a large database of existing experimental data. In addition, from the experimental database, a new confinement model for confined strength of concrete and the associated strain in the concrete are proposed, Equations 3.64 and 3.65. It was concluded that the proposed models performed more accurately than the existing models based on the root mean squared error (RMSE) analysis and the coefficient of variance ($R^2$) analysis. The second
Several seismic retrofit design guidelines and approaches were analyzed and also modified using the confinement models deemed most accurate earlier. Two sample columns, one deficient in shear, and the other deficient in flexure were used as test cases. It was concluded that, when design thicknesses were compared with experimental data from a column tested that for a shear column, the Caltrans Memo 20-4 [5] approach was most appropriate when the desired ductility was above 6.5 and the Seible et al. [43] approach is most suitable when the desired ductility is below 6.5. However, it was proposed that the Caltrans Memo 20-4 [5] could be used for lower ductilities with a reduction factor to account for the over conservativeness. Similarly, for a flexural column, it was determined that the Seible et al. [43] approach was most appropriate for all cases.

In contrast to the seismic design approaches, a new approach using the strain levels in the reinforcement at each damage state was proposed. This strain based design, used sectional analysis to determine the decrease in axial load carrying capacity of the column at the strain level for the damage state being considered. Using the loss of axial capacity, a required confined strength that the FRP jacket would need to restore the original axial capacity was determined. From the required confined strength, a design thickness can be found. Three approaches were analyzed, the Caltrans Memo 20-4 [5], the proposed strength model and Girgin’s [13] strength model. When compared with an experimental column that was classified as damage state DS-4, which was repaired using a CFRP jacket and then tested to failure, the proposed strength model was the most
appropriate approach in determined a design thickness. The main advantage to the strain
based approach, as opposed to the seismic retrofit design is that the design thickness
decrease as the damage state decreases; therefore, better utilizing the material and
creating a more economical design.

8.2 Considerations for Construction

Before this research is implemented, detailed guidelines for construction should be generated. Field conditions and construction approaches can greatly affect the performance of FRP jackets. A few suggestions for construction are presented here.

Column surfaces should be cleaned and loose concrete should be cleared before applying the FRP jacket. Large holes or spalled areas should be filled with an epoxy grout to create a smooth surface for the FRP to bond to. Quality control measures should be employed to ensure the FRP jacket is applied correctly. Measures should be taken to monitor cure conditions to ensure full cure before opening the bridge for use.

8.3 Future Research

The goal of this thesis was to move forward in the research areas discussed within and to present a baseline for a decision tree to be expanded upon. There are several areas that could use more research to validate or expand the research presented here. The following areas could use more research:

1. More extensive research for the strain levels associated with each damage state is needed. The strain levels presented within this thesis are based on a very limited set of tests.
2. Most tests conducted to validate the damage state strain, the design models and the strain based design approach were conducted on small scale specimens. More research to validate using large scale specimens is needed.

3. Design models and strain based design were validated for carbon/epoxy FRP jackets only. Research to validate equations for GFRP and AFRP is needed.

4. Experimental validation of the decision tree is needed to eliminate further conservatism.

5. The effect of bond between the FRP jacket and the concrete needs to be explored.

6. Research to further expand the decision tree for other column geometries is needed.

To achieve ductility of 6:

**Inside Plastic Hinge**:

\[ f_l = 2068 \cdot 10^3 \text{ Pa} \]

\[ e_{cc} = 0.004 \]

\[ t_f = \frac{f_t}{2 \cdot 0.5 \cdot E_f \cdot e_{cc}} \]

\[ t_f = 1.412 \text{ mm} \]

**Outside Plastic Hinge**:

\[ f_l = 1034 \cdot 10^3 \text{ Pa} \]

\[ e_{cc} = 0.004 \]

\[ t_f = \frac{f_t}{2 \cdot 0.5 \cdot E_f \cdot e_{cc}} \]

\[ t_f = 0.706 \text{ mm} \]

\[ f_t = 0.183 \text{ mm}^2 \text{ N}^{-1} \]

Recommended Confining Pressure

\[ t_f = \frac{f_t \cdot D \cdot \phi_f^2}{2 \cdot E_f} \]

\[ t_f = 0.534 \text{ mm} \quad \text{and} \quad t_f = 0.021 \text{ in} \]

ISIS Canada Network of Centers of Excellence (2001)

\[ \alpha_{pc} := 1.0 \quad \text{For circular columns} \]

\[ f_{fmax} := \frac{0.29f_c}{\alpha_{pc}} \quad \text{Recommended Maximum Confining Pressure} \]

\[ f_{fmax} = 9.991 \text{ MPa} \]

\[ \phi_{fpr} := 0.75 \]

\[ f_t = \frac{2 \cdot \phi_{fpr} \cdot E_f \cdot \phi_f \cdot t_f}{D} \]

\[ t_f = \frac{f_{fmax} \cdot D}{2 \cdot \phi_{fpr} \cdot E_f \cdot \phi_f} \]

\[ t_f = 3.103 \text{ mm} \quad t_f = 0.122 \text{ in} \]

Associated Confined Strength of Concrete, \( f_{cc} \):

\[ f_{cc} = 0.6 \]

\[ w_f := \frac{2 \cdot f_{fmax}}{f_c \cdot \phi_c} \quad w_f = 0.967 \]

\[ f_{cc} := f_c \cdot \left( 1 + \alpha_{pc} \cdot w_f \right) \]

\[ f_{cc} = 67.752 \text{ MPa} \]
Seible et al. (1997)

Shear Strengthening

\[ V_o = \frac{1.5 \cdot M_{xy}}{H} \] \hspace{1cm} \text{Shear Demand}

\[ V_o = 795.81 \text{ kN} \]

\[ V_c = 0 \text{ kN} \] \hspace{1cm} \text{Ignore Shear Contribution from Concrete, since concrete is damaged}

\[ \theta = 45 \text{deg} \] \hspace{1cm} \text{Assumed angle of shear crack, this is conservative}

\[ D_e = D - 2 \cdot c_e - d_h \] \hspace{1cm} \text{Effective Column Diameter}

\[ V_s = \frac{\pi}{2} \cdot \frac{A_h \cdot f_y \cdot D_e}{s} \cdot \cot(\theta) \] \hspace{1cm} \text{Shear Contribution from Steel Reinforcement}

\[ V_s = 66.074 \text{ kN} \]

\[ V_p = \frac{P \cdot (D - c_u)}{H} \] \hspace{1cm} \text{Shear Contribution from Axial Load}

\[ V_p = 111.042 \text{ kN} \]

\[ \phi_v = 0.83 \]

\[ t_v = \frac{V_o}{\phi_v \cdot (V_o + V_s + V_p)} \]

\[ t_v = \frac{2}{\frac{2}{2} \cdot 0.004 \cdot E_p \cdot D} \]

\[ t_v = 1.594 \text{ mm} \]

\[ t_v = 0.122 \text{ m} \]
Flexural Strengthening

Assume Desired Ductility is 8

\[ \mu_\Delta := 8 \]

\[ L_p = 0.08 \cdot \frac{H}{2} + 0.022 \cdot f_y \cdot d_b \]  
**Plastic Hinge Length for Double Bending**

\[ L_p := 223.52 \text{mm} \]

\[ \mu_\Phi := 1 + \frac{\mu_\Delta - 1}{3 \cdot \left( \frac{L_p}{H} \right) \cdot \left[ 1 - 0.5 \left( \frac{L_p}{H} \right) \right]} \]

\[ \mu_\Phi = 15.01 \]

\[ \varepsilon_{cu} := \mu_\Phi \cdot \Phi_y \cdot \varepsilon_u \]

\[ \varepsilon_{cu} = 0.014 \]

\[ \varepsilon_{cu} = 0.004 + \frac{2.8 \cdot f_y \cdot \varepsilon_f}{f_{ce}} \]

\[ \phi_f := 0.9 \]

\[ f_{ce} := 1.5 \cdot f_c \]  
**Assumed Confined Strength of Concrete, conservative**

\[ t_{e1} \geq \frac{0.09 \cdot D \cdot (\varepsilon_{cu} - 0.004) \cdot f_{ce}}{\phi_f \cdot f_y \cdot 0.01} \]

\[ t_{e1} = 2.331 \text{mm} \]

\[ t_{e1} = 0.122 \text{in} \]

\[ t_{e2} \geq \frac{t_{e1}}{2} \]

\[ t_{e2} = 1.166 \text{mm} \]

\[ t_{e2} = 0.122 \text{in} \]
Assume Desired Ductility if 10

\[ \mu_A := 10 \]

\[ L_p = 0.08 \cdot \frac{H}{2} + 0.022 \cdot f_y \cdot d_i \]

Plastic Hinge Length for Double Bending

\[ L_p := 223.52 \text{mm} \]

\[ \mu_\phi := 1 + \frac{\mu_A - 1}{3 \cdot \left( \frac{L_p}{H} \right) \cdot \left[ 1 - 0.5 \cdot \left( \frac{L_p}{H} \right)^2 \right]} \]

\[ \mu_\phi := 19.012 \]

\[ \varepsilon_{cu} := \mu_\phi \cdot f_y \cdot c_u \]

\[ \varepsilon_{cu} = 0.017 \]

\[ \varepsilon_{cu} = 0.004 + \frac{2.8 \cdot p_i \cdot f_y \cdot \varepsilon_{fr}}{f_{cc}} \]

\[ \varepsilon_{fr} = 0.9 \]

\[ f_{cc} := 1.5 \cdot f_c \]

Assumed Confined Strength of Concrete, conservative

\[ t_{cl1} := \frac{0.09 \cdot D \cdot (f_{cu} - 0.004) \cdot f_{cc}}{\phi_f \cdot f_y \cdot 0.01} \]

\[ t_{cl1} = 3.21 \text{ mm} \]

\[ t_{cl1} = 0.126 \text{ in} \]

\[ t_{cl2} := \frac{t_{cl1}}{2} \]

\[ t_{cl2} = 1.665 \text{ mm} \]

\[ t_{cl2} = 0.063 \text{ in} \]

**Lap Splice Clamping**

This column does not contain a lap splice
Modifications using the top two confinement models described in chapter 3

Top Strength Models:

Proposed Model:

\[ f_{cc} = f_{cc}' \left[ -0.503 \cdot \left( \frac{f_{c}}{f_{cc}'} \right)^2 + 2.7798 \cdot \frac{f_{t}}{f_{cc}'} + 0.9469 \right] \]

Girgin's Hoek-Brown Model:

\[ f_{cc} = f_{t} + \sqrt{f_{c}^2 + 3.5 \cdot f_{c} \cdot f_{t}} \]

Top Strain Models:

Proposed Model:

\[ \varepsilon_{cc} = \varepsilon_{cc}' \left[ 1.0427 \cdot \left( \frac{\varepsilon_{cc}'}{\varepsilon_{cc}} \right)^2 - 1.1181 \cdot \frac{f_{cc}}{f_{c}} + 6.1949 \right] \]

Mander et al's Model:

\[ \varepsilon_{cc} = \varepsilon_{cc}' \left[ 1 + 5 \cdot \left( \frac{\varepsilon_{cc}'}{\varepsilon_{cc}} - 1 \right) \right] \]

ACI 440.2R-02 (2002)

Axial Capacity Design Using Proposed Strength Model

\[ k_{e} := 0.85 \quad \text{For spiral reinforced columns} \]
\[ \phi := 0.75 \]
\[ \Psi_{f} := 0.95 \quad \text{For wrapped column jackets} \]

\[ A_{h} := \frac{\pi \cdot D^2}{4} \quad A_{b} = 0.292 \text{m}^2 \]

\[ \phi \cdot P_{h} = k_{e} \cdot \phi \cdot \left[ 0.85 \cdot \Psi_{f} \cdot f_{cc} \cdot \left( A_{h} - A_{b} \right) + f_{y} \cdot A_{b} \right] \]

Want \( \phi P_{h} \) to equal axial load (591.61kN)

\[ P = k_{e} \cdot \phi \cdot \left[ 0.85 \cdot \Psi_{f} \cdot f_{cc} \cdot \left( A_{h} - A_{b} \right) + f_{y} \cdot A_{b} \right] \]
Required confining strength to achieve axial load given:

\[ f_{cc} = \frac{p}{k_{0} \cdot \phi} - \frac{f_{c} \cdot A_{s}}{0.85 \cdot f_{y} \cdot (A_{g} - A_{s})} \]

\[ f_{cc} = 3.571 \text{ MPa} \]

For circular columns:

\[ k_{0} = 1.0 \]

Volumetric ratio of FRP:

\[ \rho_{f} = \frac{4 \cdot t_{f}}{D} \]

Confining Pressure:

\[ f_{c} = \frac{k_{s} \cdot \rho_{f} \cdot e_{fd} \cdot E_{f}}{3} \]

\[ f_{i} = \frac{2 \cdot k_{s} \cdot t_{f} \cdot e_{fd} \cdot E_{f}}{D} \]

\[ f_{cc} = f_{c} \left[ -0.503 \cdot \left( \frac{f_{i}}{f_{c}} \right)^{2} + 2.7798 \cdot \frac{f_{i}}{f_{c}} + 0.9469 \right] \]

\[ 3.571 = 34.45 \left[ 0.9469 + 0.503 \cdot \left( \frac{2 \cdot t_{f} \cdot 1310}{610 \cdot 34.45} \right)^{2} + 2.7798 \cdot \frac{2 \cdot t_{f} \cdot 1310}{610 \cdot 34.45} \right] \]

Thickness is negative; therefore, no FRP required for axial capacity.

Axial Capacity Design Using Girgin's Strength Model:

Girgin Goek-Brown Model:

\[ f_{cc} = f_{i} + \sqrt{f_{c}^{2} + 3.5 \cdot f_{c} \cdot f_{i}} \]

\[ 3.571 = \frac{2 \cdot t_{f} \cdot 1310}{610} + \sqrt{34.45^{2} + 3.5 \cdot 34.45 \cdot \frac{2 \cdot t_{f} \cdot 1310}{610}} \]

Thickness is negative; therefore, no FRP required for axial capacity.
Seismic Design Using ACI 440 Strain Model and Proposed Strength Model

Assume given ductility desire is 8

\[ \mu_A := 8 \]

\[ L_p = 0.08 \cdot \frac{H}{2} + 0.022 \cdot f_y \cdot d_b \]

Plastic Hinge Length for Double Bending

\[ L_p = 223.82 \text{mm} \]

\[ \mu_B := 1 + \frac{\mu_A - 1}{3 \cdot \frac{H}{2} \cdot \left[ 1 - 0.5 \cdot \frac{L_p}{H/2} \right]} \]

\[ \mu_B = 15.01 \]

\[ \varepsilon_{cc} := \mu_B \cdot \varepsilon_y \cdot \varepsilon_u \]

\[ \varepsilon_{cc} = 0.014 \]

Confined Concrete Strain

\[ \varepsilon_e = 1.71 \cdot \frac{\varepsilon_{cc} - 4 \cdot f_c}{f_c} \]

\[ f_{cc} = \frac{f_{cc} \cdot E_c}{1.71} + 4 \cdot f_c \]

\[ f_{cc} = \frac{5}{4} \cdot f_{ee} \]

Required confined strength of concrete

\[ f_{cc} = 71.714 \text{MPa} \]

\[ \varepsilon_{fd} = \min \left( 0.004, 0.075 \varepsilon_u \right) \]

\[ \varepsilon_{fd} = 4 \times 10^{-3} \]

\[ f_l = \frac{k_0 \cdot f_y - \varepsilon_{fd} \cdot E_f}{2} \]

\[ f_l = 2 \cdot k_0 \cdot f_y \cdot \varepsilon_{fd} \cdot E_f \]

\[ f_{cc} = f_{cc} \left[ -0.503 \cdot \left( \frac{1}{f_c} \right)^2 + 2.7798 \cdot \frac{f_l}{f_c} + 0.9469 \right] \]

\[ f_{cc} = 71.714 \left[ 0.9469 + -0.503 \left( \frac{2 \cdot f_{ld} - 1310}{610 \cdot 34.45} \right)^2 + 2.7798 \frac{2 \cdot f_{ld} - 1310}{610 \cdot 34.45} \right] \]

solve \( f_{ld} \rightarrow 3.5602451623889682144 \)

\[ 10.766244070154683067 \]
Assume given ductility desire is 10:

\[ \mu_D := 10 \]

\[ L_p := 0.08 \cdot \frac{H}{2} + 0.022 \cdot \xi \cdot d_b \]

Plastic Hinge Length for Double Bending

\[ L_p := 223.62 \text{mm} \]

\[ \mu_{ph} := 1 + \frac{\mu_D - 1}{3 \cdot \left( \frac{L_p}{H} \right) \left[ 1 - 0.5 \cdot \left( \frac{L_p}{H} \right) \right]} \]

\[ \mu_{ph} = 19.94 \]

\[ \varepsilon_{cc} := \mu_{ph} \cdot \Phi_Y \cdot \varepsilon_u \]

\[ \varepsilon_{cc} = 0.017 \]

Confined Concrete Strain

\[ \varepsilon_{cc} = 1.71 \cdot \frac{5 \cdot \varepsilon_{co} - 4 \cdot \varepsilon_c}{E_c} \]

\[ \varepsilon_{cc} = \frac{\varepsilon_{cc} \cdot E_c}{1.71} + 4 \cdot \varepsilon_c \]

\[ f_{cc} := \frac{1.71 \cdot 4 \cdot f_c}{5} \]

Required confined strength of concrete

\[ f_{cc} = 83.489 \text{MPa} \]

\[ \varepsilon_{fd} := \min \{0.004, 0.75 \varepsilon_f\} \]

\[ \varepsilon_{fd} = 4 \times 10^{-3} \]

\[ f_1 = k_s \cdot \varepsilon_f \cdot E_f \]

\[ f_1 = \frac{2 \cdot k_s \cdot \varepsilon_f \cdot E_f}{D} \]

\[ f_{cc} = f_c \cdot \left[ -0.503 \cdot \left( \frac{f_f}{f_c} \right)^2 + 2.779 \cdot \frac{f_f}{f_c} + 0.9469 \right] \]
83.489 \implies 34.45 \left[ 0.9469 + 0.503 \left( \frac{2 \cdot t_{f2} \cdot 1310}{610 \cdot 34.45} \right)^2 + 2 \cdot 2.7708 \cdot \frac{2 \cdot t_{f2} \cdot 1310}{610 \cdot 34.45} \right] \implies \text{solve,} t_{f2} \implies 4.77, \text{solve,} t_{f2} \implies 0.1188 \text{ in}

\text{or}

\[t_{f} := 4.02 \text{ mm} \quad t_f := 0.158 \text{ in}\]
Seismic Design Using Mander et al's Strain Model and ACI 440 Strength Model

Assume given ductility desire is 8:

\[ \mu_\Delta := 8 \]

\[ \Gamma_p := 0.08 \cdot \frac{H}{2} + 0.022 \cdot f_y \cdot d_p \]  
Plastic Hinge Length for Double Bending

\[ \Gamma_p := 223.52\text{mm} \]

\[ \mu_\phi := 1 + \frac{\mu_\Delta - 1}{3 \cdot \left( \frac{\Gamma_p}{H} \right) \cdot \left[ 1 - 0.5 \cdot \left( \frac{f_y}{H} \right)^2 \right]} \]

\[ \mu_\phi = 15.01 \]

\[ \varepsilon_{cc} := \mu_\phi \cdot f_y \cdot \varepsilon_u \]

\[ \varepsilon_{cc} = 0.0137 \]  
Confined Concrete Strain

Mander et al's Strain Model:

\[ \varepsilon_{cc} = \varepsilon_{cc} \cdot \left[ 1 + 5 \cdot \left( \frac{f_{cc}}{f_c} - 1 \right) \right] \]

0.0137 \cdot 0.002 \cdot \left[ 1 + 5 \cdot \left( \frac{f_{cc}}{f_c} \right) \cdot \frac{34.45}{34.45} - 1 \right] \rightarrow 74.75655000000000000001

\[ f_{cc} := 74.76\text{MPa} \]  
Required Confined Strength of Concrete

\[ \varepsilon_{d1} := \min \left( 0.004, 0.75 \varepsilon_f \right) \]

\[ \varepsilon_{d1} = 4 \times 10^{-3} \]

\[ \varepsilon_{d1} = \frac{k_s \cdot \varepsilon_f \cdot \varepsilon_{d1} \cdot E_F}{2} \]

\[ f_l = \frac{2 \cdot k_s \cdot f_y \cdot \varepsilon_{d1} \cdot E_f}{D} \]

\[ f_{cc} = f_c \cdot \left( 2.25 \cdot \sqrt{1 + 7.9 \cdot \frac{1}{f_c} - 2 \cdot \frac{f_l}{f_c} - 1.25} \right) \]

74.76 \text{ MPa} = 34.45 \text{ MPa} \cdot \left[ 2.25 \cdot \sqrt{1 + 7.9 \cdot \frac{1}{f_c} - 2 \cdot \frac{f_l}{f_c} - 1.25} \cdot \frac{124.1 \text{ MPa}}{34.45 \text{ MPa}} \right] \rightarrow 5.58905651333647879 \cdot 10^{-3} \cdot \text{m}

130
\[ t_F = 0.134 \text{m} \quad t_f = 134 \text{mm} \]

or

\[ t_F = 0.00556 \text{m} \quad t_f = 5.56 \text{mm} \quad t_f = 0.219 \text{in} \]

Assume given ductility desire is 10:

\[ \mu_{\Delta} := 10 \]

\[ L_p = 0.08 \cdot \frac{H}{2} + 0.022 \cdot f_y \cdot d_b \]

Plastic Hinge Length for Double Bending

\[ L_p = 223.52 \text{mm} \]

\[ \mu_{\phi} := 1 + \frac{\mu_{\Delta} - 1}{3 \cdot \left( \frac{L_p}{H} \right) \cdot \left( 1 - 0.5 \cdot \left( \frac{L_p}{H} \right) \right)} \]

\[ \mu_{\phi} = 19.012 \]

\[ \sigma_{cc} := \mu_{\phi} \cdot \phi \cdot \sigma_u \quad \sigma_{cc} = 0.0173 \]

Confined Concrete Strain

Mander et al's Strain Model:

\[ \sigma_{cc} = \sigma_{co} \left[ 1 + 5 \cdot \left( \frac{\sigma_{cc}}{f_c} \right)^{3.4} \right] \]

0.0173 \approx 0.002 \left[ 1 + 5 \cdot \left( \frac{f_{cc}}{34.45} \right)^{3.4} \right] \Rightarrow f_{cc} \rightarrow 87.1585 \text{MPa}

\[ f_{cc} := 87.16 \text{MPa} \]

Required Confined Strength of Concrete

\[ \sigma_{\text{fl}} := \min (0.004, 0.7 \sigma_{f}) \quad \sigma_{\text{fl}} = 4 \times 10^{-3} \]

\[ f_1 = \frac{k_b \cdot f_y \cdot \sigma_{fl} \cdot E_f}{2} \quad f_1 = \frac{2 \cdot k_b \cdot f_y \cdot \sigma_{fl} \cdot E_f}{D} \]

\[ f_{ce} = f_c \cdot \left( 2.25 \cdot \sqrt{1 + 7.9 \cdot \frac{g_1}{f_c}} - 2 \cdot \frac{g_1}{f_c} - 1.25 \right) \]
Seismic Design Using Mander et al. 's Strain Model and Proposed Strength Model

Assume given ductility desire is 8:

\[ f'_{oc} = 74.76 \text{MPa} \quad \text{From Above Calculations} \]

\[
\frac{f'_{oc}}{f_c} = \frac{0.503 \left( \frac{f}{f_c} \right)^2 + 2.7798 \cdot \frac{f}{f_c} + 0.9469}{0.9469 - 0.503 \cdot \frac{2 \cdot f_c^2 \cdot 1510}{610 \cdot 34.45} + 2.7798 \cdot \frac{2 \cdot f_c^2 \cdot 1510}{610 \cdot 34.45}} \]

\[ 74.76 = 34.45 \left[ 0.9469 - 0.503 \left( \frac{2 \cdot f_c^2 \cdot 1510}{610 \cdot 34.45} \right) + 2.7798 \cdot \frac{2 \cdot f_c^2 \cdot 1510}{610 \cdot 34.45} \right] \]

solve, \( t'_{c} = 8.39 \text{ in} \)

or

\[ t'_{c} = 0.00839 \text{in} \]

Assume given ductility desire is 10:

\[ f'_{oc} = 87.16 \text{MPa} \quad \text{From Above Calculations} \]

\[
\frac{f'_{oc}}{f_c} = \frac{0.503 \left( \frac{f}{f_c} \right)^2 + 2.7798 \cdot \frac{f}{f_c} + 0.9469}{0.9469 - 0.503 \cdot \frac{2 \cdot f_c^2 \cdot 1510}{610 \cdot 34.45} + 2.7798 \cdot \frac{2 \cdot f_c^2 \cdot 1510}{610 \cdot 34.45}} \]

\[ 87.16 = 34.45 \left[ 0.9469 - 0.503 \left( \frac{2 \cdot f_c^2 \cdot 1510}{610 \cdot 34.45} \right) + 2.7798 \cdot \frac{2 \cdot f_c^2 \cdot 1510}{610 \cdot 34.45} \right] \]

solve, \( t'_{c} = 3.87 \text{ in} \)

or

\[ t_{c2} = 2.64\text{mm} \]

\[ t_{c2} = 0.104\text{in} \]
Flexural Design Example

Column Section Properties:

- $H = 3638\text{mm}$  Column Height
- $D = 610\text{mm}$  Column Diameter
- $c_c = 99.06\text{mm}$  Concrete Cover
- $f_c = 34.45\text{MPa}$  Unconfined Concrete Strength
- $E_c = 27580\text{MPa}$  Modulus of Concrete

Longitudinal Reinforcement Properties (Grade 40):

- $d_b = 19\text{mm}$  Bar Diameter, 26 in total
- $A_b = 284\text{mm}^2$  Total Bar Area
- $f_y = 300\text{MPa}$  Yield Strength

Transverse Reinforcement Properties (Grade 40):

- $d_b = 6.35\text{mm}$  Bar Diameter
- $A_b = 31.7\text{mm}^2$  Bar Area
- $s = 127\text{mm}$  Spacing

Column Load Properties:

- $P = 1800\text{kN}$  Axial Load
- $M_{y1} = 518.4\text{kN} \cdot \text{m}$  Yield Moment
- $\phi_y = 0.008196\frac{1}{\text{m}}$  Yield Curvature
- $e_n = 136.6\text{mm}$  Neutral Axis

Note: Moment, curvature and neutral axis were obtained through a moment curvature software program.

Jacket Material Properties:

- $E_f = 124.1\text{GPa}$  Jacket Modulus
- $f_u = 1310\text{MPa}$  Jacket Ultimate Strength

- $\varepsilon_f = \frac{f_u}{E_f}$  Jacket Ultimate Strain
- $\varepsilon_f = 0.011$  Jacket Ultimate Strain
ACI 440.2R-02 (2002)

Axial Capacity Design

\[ k_g := 0.85 \quad \text{For spiral reinforced columns} \]

\[ \phi := 0.75 \]

\[ \Psi_f := 0.95 \quad \text{For wrapped column jackets} \]

\[ A_g := \frac{\pi \cdot D^2}{4} \quad A_g = 0.292 \text{m}^2 \]

\[ \phi \cdot P_n = k_g \cdot \phi \cdot \left[ 0.85 \cdot \Psi_f \cdot f_{cc} \cdot (A_g - A_b) + f_y \cdot A_b \right] \]

Want \( P \) in to equal axial load (591.61kN)

\[ P = k_g \cdot \phi \cdot \left[ 0.85 \cdot \Psi_f \cdot f_{cc} \cdot (A_g - A_b) + f_y \cdot A_b \right] \]

\[ f_{cc} := \frac{p}{k_g \cdot \phi \cdot f_y \cdot A_b} \]

\[ f_{cc} = 11.61 \text{ MPa} \quad \text{Required confining strength to achieve axial load given} \]

\[ k_b := 1.0 \quad \text{For circular columns} \]

\[ \rho_f = \frac{4 \cdot t_f}{D} \quad \text{Volumetric ratio of FRP} \]

\[ \varepsilon_{fl} := \min(0.004, 0.75\varepsilon_f) \quad \varepsilon_{fl} = 4 \times 10^{-3} \]

\[ f_l = k_s \cdot \rho_f \cdot \varepsilon_{fl} \cdot E_f \]

\[ f_l = \frac{2 \cdot k_s \cdot \rho_f \cdot \varepsilon_{fl} \cdot E_f}{D} \]

\[ f_{cc} = f_c \cdot \left( 2.25 \cdot \sqrt{1 + 7.9 \cdot \frac{f_l}{f_c} - 2 \cdot \frac{f_l}{f_c} - 1.25} \right) \]

Confining Pressure
11.611 · MPa = 34.45 · MPa · \left[ -1.25 + 2.25 \cdot \left[ \sqrt{1 + 7.9 \cdot \frac{2 \cdot t_f \cdot \left( 1.4 \cdot 10^{-3} \cdot 124.1 \cdot \text{GPa} \right)}{34.45 \cdot \text{MPa} \cdot 0.61 \cdot \text{m}} - 2 \cdot \frac{2 \cdot t_f \cdot \left( 1.4 \cdot 10^{-3} \cdot 124.1 \cdot \text{GPa} \right)}{34.45 \cdot \text{MPa} \cdot 0.61 \cdot \text{m}} \right] \right] \text{ solve, } t_f \rightarrow \left[ \frac{1.952435503734277146 \cdot 10^{-3}}{2.8825867364438321645 \cdot 10^{-2}} \right].

Thickness is negative; therefore, no FRP required for axial capacity. \( t_f = 0 \)

**Seismic Design**

Assume given ductility desire is 8

\[ f_{\text{max}} = \frac{0.29f_c}{\alpha_{pc}} \]

Recommended Maximum Confining Pressure

\[ f_{\text{max}} = 9.991 \text{ MPa} \]

\[ \phi_{trp} := 0.75 \]

\[ f_l = \frac{2 \cdot \phi_{trp} \cdot E_f \cdot f_e \cdot t_f}{D} \]

\[ t_f = \frac{f_{\text{max}} \cdot D}{2 \cdot \phi_{trp} \cdot E_f \cdot f_e} \]

\[ t_f = 3.101 \text{ mm} \]

\[ t_f = 0.122 \text{ in} \]

Associated Confining Strength of Concrete, \( f_{cc} \):

\[ \phi_c := 0.6 \]

\[ w_w := \frac{2 \cdot f_{\text{max}}}{\phi_c \cdot f_c} \]

\[ w_w = 0.967 \]

\[ f_{cc} := f_c \cdot \left(1 + \alpha_{pc} \cdot w_w\right) \]

\[ f_{cc} = 67.752 \text{ MPa} \]
Seible et al. (1997)

Shear Strengthening

\[ V_o := \frac{1.5 \cdot M_{yi}}{H} \quad \text{Shear Demand for Single Bending} \]

\[ V_o = 212.657 \text{kN} \]

\[ V_c := 0 \text{kN} \quad \text{Ignore Shear Contribution from Concrete, since concrete is damaged} \]

\[ \theta := 45 \text{deg} \quad \text{Assumed angle of shear crack, this is conservative} \]

\[ D_e := D - 2 \cdot \alpha_c - d_h \quad \text{Effective Column Diameter} \]

\[ V_s := \frac{\pi}{2} \cdot \frac{A_{sl} \cdot f_y \cdot D^3}{s} \cdot \cot(\theta) \quad \text{Shear Contribution from Steel Reinforcement} \]

\[ V_s = 67.276 \text{kN} \]

\[ V_p := \frac{P \cdot (D - c_u)}{H} \quad \text{Shear Contribution from Axial Load} \]

\[ V_p = 233.045 \text{kN} \]

\[ \phi_v := 0.85 \]

\[ t_v := \frac{V_o}{\phi_v} \left( V_o + V_s + V_p \right) \]

\[ t_v = \frac{\pi}{2} \cdot 0.004 \cdot E_P \cdot D \]

\[ t_v = 0.105 \text{mm} \quad t_v = 0.122 \text{in} \]
Flexural Strengthening

Assume Desired Ductility is 8

\[ \mu_\Delta = 8 \]

\[ L_p = 0.08 \cdot H + 0.022 \cdot f_y \cdot d_b \]

Plastic Hinge Length for Single Bending

\[ L_p = 419.5 \text{ mm} \]

\[ \mu_\Phi := 1 + \frac{\mu_\Delta - 1}{3 \cdot \left( \frac{1}{H} \right)} \left[ 1 - 0.5 \left( \frac{L_p}{H} \right) \right] \]

\[ \mu_\Phi = 22.584 \]

\[ \varepsilon_{cu} := \mu_\Phi \cdot \Phi_y \cdot \varepsilon_u \]

\[ \varepsilon_{cu} = 0.025 \]

\[ \varepsilon_{cu} = 0.004 + \frac{2.8 \rho_f \cdot f_y \cdot \varepsilon_f}{f_{ce}} \]

\[ \Phi_f := 0.9 \]

\[ f_{ce} := 1.5 \cdot f_c \]

Assumed Confined Strength of Concrete, conservative

\[ t_{c1} = \frac{0.09 \cdot D \cdot (f_{cu} - 0.004) \cdot f_{ce}}{\Phi_f \cdot \varepsilon_f \cdot 0.01} \]

\[ t_{c1} = 5.113 \text{ mm} \]

\[ t_{c1} = 0.201 \text{ in} \]

\[ t_{c2} = \frac{t_{c1}}{2} \]

\[ t_{c2} = 2.556 \text{ mm} \]

\[ t_{c2} = 0.101 \text{ in} \]
Assume Desired Ductility if 10

\[ \mu_\Delta := 10 \]

\[ l_p = 0.08 \cdot H + 0.022 \cdot f_y \cdot d_b \]

Plastic Hinge Length for Single Bending

\[ l_p = 419.5 \text{ mm} \]

\[ \mu_\Phi := 1 + \frac{\mu_\Delta - 1}{3 \cdot \left( \frac{1}{H} \right) \left[ 1 - 0.5 \left( \frac{l_p}{H} \right) \right]} \]

\[ \mu_\Phi = 28.751 \]

\[ e_{cu} := \mu_\Phi \cdot f_y \cdot \epsilon_u \]

\[ e_{cu} = 0.032 \]

\[ f_{cu} = 0.004 + \frac{2.8f_y \cdot f_y \cdot \epsilon_f}{f_{cc}} \]

\[ f_{cc} := 1.5 \cdot f'_c \]

Assumed Confined Strength of Concrete, conservative

\[ t_{c1} := \frac{0.09 \cdot D \cdot \left( f_{cu} - 0.004 \right) \cdot f_{cc}}{\Phi_f \cdot f'_y \cdot 0.01} \]

\[ t_{c1} = 6.772 \text{ mm} \]

\[ t_{c1} = 0.267 \text{ in} \]

\[ t_{c2} := \frac{t_{c1}}{2} \]

\[ t_{c2} = 3.386 \text{ mm} \]

\[ t_{c2} = 0.133 \text{ in} \]
Lap Splice Clamping

\( L_s := 381 \text{mm} \quad \text{Lap Splice Length} \)

\( p := 3.208 \times 10^3 \text{mm} \quad \text{Perimeter of Column} \)

\( n := 26 \quad \text{Number of Longitudinal Bars} \)

\( A_s = 284 \text{mm}^2 \)

\[ f_t = \frac{A_s \cdot f_y}{\left( \frac{p}{2 \cdot n} + 2 \cdot (d_b + \infty) \right) \cdot L_s} \quad \text{Confining Pressure Required} \]

\( f_t = 1.641 \text{MPa} \)

\( E_s := 29000 \text{ksi} \quad \text{Modulus of Steel} \)

\[ f_h = \frac{0.002 \cdot A_h \cdot E_s}{D \cdot s} \]

\( f_h = 0.164 \text{MPa} \quad \text{Confining Pressure Provided by Spiral Hoops} \)

\[ t_s = \frac{500 \cdot D \cdot (f_l - f_h)}{E_f} \]

\( t_s = 3.632 \text{mm} \quad t_f = 0.122 \text{in} \)
Modifications using the top two confinement models described in chapter 3

Top Strength Models:

Proposed Model:

\[ f_{cc} = f_{c} \cdot \left[ -0.503 \cdot \left( \frac{f_{y}}{f_{c}} \right)^{2} + 2.7798 \cdot \frac{f_{y}}{f_{c}} + 0.9469 \right] \]

Girgin's Hoek-Brown Model:

\[ f_{cc} = f_{t} + \sqrt{f_{c}^{2} + 3.5 \cdot f_{c} \cdot f_{t}} \]

Top Strain Models:

Proposed Model:

\[ \varepsilon_{cc} = \varepsilon_{cc} \cdot \left[ 1.0427 \cdot \left( \frac{f_{cc}}{f_{c}} \right) - 1.1181 \cdot \frac{f_{cc}}{f_{c}} + 6.1949 \right] \]

Mender et al.'s Model:

\[ \varepsilon_{cc} = \varepsilon_{cc} \cdot \left[ 1 + 5 \cdot \left( \frac{f_{cc}}{f_{c}} - 1 \right) \right] \]

ACI 440.2R-02 (2002)

Axial Capacity Design Using Proposed Strength Model:

- \[ k_{e} = 0.85 \quad \text{For spiral reinforced columns} \]
- \[ \phi = 0.75 \]
- \[ \Psi_{f} = 0.95 \quad \text{For wrapped column jackets} \]

\[ A_{g} = \frac{\pi \cdot D^{2}}{4} \quad A_{g} = 0.292 \text{m}^{2} \]

\[ \phi \cdot P_{n} = k_{e} \cdot \phi \cdot \left[ 0.85 \cdot \Psi_{f} \cdot f_{cc} \cdot (A_{g} - A_{s}) + f_{y} \cdot A_{s} \right] \]

Want \( \phi P_{n} \) to equal axial load (591.61kN)

\[ P = k_{e} \cdot \phi \cdot \left[ 0.85 \cdot \Psi_{f} \cdot f_{cc} \cdot (A_{g} - A_{s}) + f_{y} \cdot A_{s} \right] \]
\[ f_{cc} := \frac{P}{k_e \cdot \phi - f_y \cdot A_s} \]

\[ f_{cc} = 11.611 \text{ MPa} \] Required confining strength to achieve axial load given

\[ k_s = 1.0 \] For circular columns

\[ \rho_f = \frac{4 \cdot t_f}{D} \] Volumetric ratio of FRP

\[ \varepsilon_{f1} = \min(0.004, 0.75 \varepsilon_{f2}) \quad \varepsilon_{f2} = 4 \times 10^{-3} \]

\[ f_1 = k_s \cdot \rho_f \cdot \varepsilon_{f1} \cdot E_f \]

\[ f_2 = \frac{2 \cdot k_s \cdot t_f \cdot \varepsilon_{f2} \cdot E_f}{D} \] Confining Pressure

\[ f_{cc} = f_c \left[ -0.503 \cdot \left( \frac{f_1}{f_c} \right)^2 + 2.7798 \cdot \frac{f_1}{f_c} + 0.9469 \right] \]

\[ 11.611 = 34.45 \left[ -0.9469 - 0.503 \left( \frac{2 \cdot t_f \cdot 1310}{610 \cdot 34.45} \right)^2 + 2.7798 \cdot \frac{2 \cdot t_f \cdot 1310}{610 \cdot 34.45} \right] \]

solving \( t_f \) gives: \( t_f = 0 \)

Axial Capacity Design Using Girgin's Strength Model

Girgin Goek-Brown Model:

\[ f_{cc} = f_1 + \sqrt{f_0^2 + 3.5 \cdot f_c - f_1} \]

\[ 11.611 = \frac{2 \cdot t_f \cdot 1310}{610} + \sqrt{34.45^2 + 3.5 \cdot 34.45 \cdot \frac{2 \cdot t_f \cdot 1310}{610}} \rightarrow t_f = 0 \]

Thickness is negative; therefore, no FRP required for axial capacity.
Seismic Design Using ACI 440 Strain Model and Proposed Strength Model

Assume given ductility desire is 8

\[ \mu_D = 8 \]

\[ L_p = 0.08 \cdot H + 0.022 \cdot f_y \cdot d_p \]  
Plastic Hinge Length for Single Bending

\[ L_p = 419.5 \text{ mm} \]

\[ \mu_p := 1 + \frac{\mu_D - 1}{3 \cdot \frac{H}{H}} \cdot \left[ 1 - 0.5 \cdot \frac{f_y}{f_y} \right] \]

\[ \mu_p = 22.584 \]

\[ \varepsilon_{c_e} := \mu_p \cdot \Phi_y \cdot \varepsilon_u \quad \varepsilon_{c_e} = 0.025 \]  
Confined Concrete Strain

\[ \varepsilon_{c_e} = 1.71 \cdot \frac{5 \cdot f_{c_e} - 4 \cdot f_c}{f_c} \]

\[ f_{c_e} = \frac{\varepsilon_{c_e} \cdot f_c}{1.71} + 4 \cdot f_c \]  
Required confined strength of concrete

\[ f_{c_e} = 109 \text{, }002 \text{ MPa} \]

\[ \varepsilon_{fd} = \min \left( 0.004, 0.75 \varepsilon_r \right) \quad \varepsilon_{fd} = 4 \times 10^{-3} \]

\[ f_1 = \frac{k_u \cdot P_1 \cdot \varepsilon_{fd} \cdot E_F}{2} \quad f_1 = \frac{2 \cdot k_u \cdot P_2 \cdot \varepsilon_{fd} \cdot E_F}{D} \]

\[ f_{c_e} = f_{c_e} \left[ -0.503 \cdot \frac{f_1}{f_c} + 2.7798 \cdot \frac{f_1}{f_c} + 0.9469 \right] \]

\[ 109 = 34.45 \left[ 0.9469 - 0.503 \left( \frac{2 \cdot f_2 \cdot 1310}{610 \cdot 34.45} \right)^2 + 2.7798 \left( \frac{2 \cdot f_2 \cdot 1310}{610 \cdot 34.45} \right) \right] \quad \text{solving, } f_2 \rightarrow \left( 7.753 \cdot 10^{3} \cdot 1369975484005 \right) \]

[Equation for solving]
\[ t_F = 36.57 \text{mm} \]

or

\[ t_F = 7.75 \text{mm} \]

\[ t_F = 0.305 \text{in} \]

Assume given ductility desire is 10:

\[ \mu_d = 10 \]

\[ L_p = 0.08 \cdot H + 0.022 \cdot f_y \cdot d_p \]

Plastic Hinge Length for Single Bending

\[ L_p = 419.5 \text{mm} \]

\[ \mu_{ph} = 1 + \frac{\mu_d - 1}{3 \cdot \left( \frac{H}{d_p} \right)^2 \cdot \left[ 1 - 0.5 \cdot \left( \frac{d_p}{H} \right) \right]} \]

\[ \mu_{ph} = 28.751 \]

\[ \varepsilon_{cc} = \mu_{ph} \cdot \Phi \cdot \varepsilon_u \]

\[ \varepsilon_{cc} = 0.032 \]

Confined Concrete Strain

\[ \varepsilon_{cc} = 1.71 \cdot \frac{5 \cdot f_{cc} - 4 \cdot f_c}{f_c} \]

\[ \frac{\varepsilon_{cc} \cdot E_c}{1.71} + 4 \cdot f_c \]

\[ f_{cc} = \frac{131.24 \text{MPa}}{5} \]

Required confined strength of concrete

\[ f_{cc} = 131.24 \text{MPa} \]

\[ \varepsilon_{fd} = \min \left( 0.004, 0.75 \varepsilon_t \right) \]

\[ \varepsilon_{fd} = 4 \times 10^{-3} \]

\[ f_{l_1} = k_s \cdot f_y \cdot E_f \]

\[ f_{l_1} = 2 \cdot k_s \cdot f_y \cdot E_f / D \]

\[ f_{cc} = f_{l_1} + 0.503 \left( \frac{f_{l_1}}{f_c} \right)^2 + 2.7798 \cdot \frac{f_{l_1}}{f_c} + 0.9469 \]
Seismic Design Using ACI 440 Strain Model and Proposed Strength Model

Assume Desired Ductility is 8

\[ f_{c0} := 109 \text{MPa} \quad \text{From above calculations} \]

\[ f_{c}' = f_{j} + \sqrt{\frac{f_{c}^2}{3} + 3.5 \cdot f_{c} \cdot f_{j}} \]

\[ 109 = \frac{2 \cdot t_{f} \cdot 1310}{610} + \sqrt{34.45^2 + 3.5 \cdot 34.45 \cdot \frac{2 \cdot t_{f} \cdot 1310}{610}} \text{ solve, } t_{f} \rightarrow 8.208790526831292042 \]

\[ t_{f} = 8.21 \text{mm} \quad t_{f} = 0.323 \text{in} \]

Assume Desired Ductility is 10

\[ f_{c0} := 131.24 \text{MPa} \quad \text{From above calculations} \]

\[ f_{c}' = f_{j} + \sqrt{\frac{f_{c}^2}{3} + 3.5 \cdot f_{c} \cdot f_{j}} \]

\[ 131.24 = \frac{2 \cdot t_{f} \cdot 1310}{610} + \sqrt{34.45^2 + 3.5 \cdot 34.45 \cdot \frac{2 \cdot t_{f} \cdot 1310}{610}} \text{ solve, } t_{f} \rightarrow 11.138684786936818766 \]

\[ t_{f} = 11.34 \text{mm} \quad t_{f} = 0.439 \text{in} \]
Seismic Design Using Proposed Strain Model and ACI 440 Strength Model

Assume given ductility desire is 8:

\( \mu_\Delta := 8 \)

\( L_p = 0.08 \cdot H + 0.022 \cdot f_y \cdot d_b \) \hspace{1cm} Plastic Hinge Length for Single Bending

\( L_p = 419.5 \text{ mm} \)

\( \mu_b := 1 + \frac{\mu_\Delta - 1}{3 \cdot \left( \frac{f_y}{f_p} \right) \left[ 1 - 0.5 \left( \frac{f_y}{f_p} \right) \right]} \)

\( \mu_b = 22.984 \)

\( e_{cc} := \mu_b \cdot f_y \cdot \rho_{ct} \quad e_{cc} = 0.0252 \) \hspace{1cm} Confined Concrete Strain

Proposed Strain Model:

\( e_{cc} = e_{cc0} \cdot \left[ 1.0427 \cdot \left( \frac{e_{cc}}{e_{cc0}} \right)^2 - 1.1181 \frac{e_{cc}}{f_p} + 6.1949 \right] \)

\( 0.0252 = 0.002 \cdot 6.1949 + 1.0427 \cdot \left( \frac{f_{cc1}}{34.45} \right)^2 - 1.1181 \frac{f_{cc1}}{34.45} \) solve, \( f_{cc1} \to \frac{-68.887623203981729130}{105.82878077567061376} \)

\( f_{cc} = 105.83 \text{ MPa} \) \hspace{1cm} Required Confined Strength of Concrete

\( e_{f1} := \min\left(0.004, 0.75e_f\right) \quad e_{f1} = 4 \times 10^{-3} \)

\( \bar{\varepsilon} = \frac{k_x \cdot \rho f \cdot E_f}{2} \quad \bar{\varepsilon} = \frac{2 \cdot k_x \cdot f_y \cdot E_f}{D} \)

\( f_{cc} = f_c \cdot \left( 2.25 \sqrt{1 + 7.9 \cdot \frac{\bar{\varepsilon}}{f_c} - 2 \cdot \frac{\bar{\varepsilon}}{f_c} - 1.25} \right) \)
\[ 105.83 \cdot \text{MPa} = 34.45 \cdot \text{MPa} \cdot \left[ \frac{2.25}{1 + 7.9} \cdot \frac{2 \cdot t_{\text{fl}} \cdot \left(4 \cdot 10^{-3} \cdot 124.1 \cdot \text{GPa}\right)}{34.45 \cdot \text{MPa} \cdot 0.61 \cdot \text{m}} \right] \approx 34.45 \cdot \text{MPa} \cdot \left(4 \cdot 10^{-3} \cdot 124.1 \cdot \text{GPa}\right) \]

or

\[ t_{\text{fl}} = 0.166 \text{m} \quad t_{\text{fl}} = 106 \text{mm} \]

\[ t_{\text{fl}} = 0.0144 \text{m} \quad t_{\text{fl}} = 14.43 \text{mm} \quad t_{\text{fl}} = 0.568 \text{in} \]

Assume given ductility desire is 10:

\[ \mu_{\Delta} := 10 \]

\[ L_p = 0.08 \cdot H + 0.022 \cdot f_y \cdot d_b \]

Plastic Hinge Length for Single Bending

\[ L_p = 41.95 \text{mm} \]

\[ \mu_{Ph} := 1 + \frac{\mu_{\Delta} - 1}{3 \cdot \left(\frac{2}{H}\right) \left[1 - 0.5 \cdot \left(\frac{2}{H}\right)\right]} \]

\[ \mu_{Ph} = 28.751 \]

\[ \varepsilon_{\text{cc}} := \mu_{Ph} \cdot \Phi_y \cdot \varepsilon_u \quad \varepsilon_{\text{cc}} = 0.0321 \quad \text{Confined Concrete Strain} \]

Proposed Strain Model:

\[ \varepsilon_{\text{cc}} = \max \left[ 0.002 \cdot \left( 6.1949 + 1.0427 \cdot \frac{\varepsilon_{\text{cc}}}{34.45} \right)^2 - 1.1181 \cdot \frac{\varepsilon_{\text{cc}}}{34.45} + 6.1949 \right] \]

\[ 0.0321 = 0.002 \cdot 6.1949 + 1.0427 \cdot \left( \frac{\varepsilon_{\text{cc}}}{34.45} \right)^2 - 1.1181 \cdot \frac{\varepsilon_{\text{cc}}}{34.45} \]

\[ \varepsilon_{\text{cc}} = 125.98 \text{MPa} \quad \text{Required Confined Strength of Concrete} \]

\[ \varepsilon_{\text{fl}} := \min \left[ 0.004, 0.75 \varepsilon_f \right] \quad \varepsilon_{\text{fl}} = 4 \times 10^{-3} \]

\[ f_l = \frac{k_1 \cdot f_y \cdot \varepsilon_{\text{fl}} \cdot E_f}{2} \quad f_l = \frac{2 \cdot k_2 \cdot t_{\text{fl}} \cdot \varepsilon_{\text{fl}} \cdot E_f}{D} \]
Seismic Design Using Proposed Strain Model and Proposed Strength Model

Assume given ductility desire is 8:

\[
\rho_{cc} = \rho'_{c} \left( 2.25 \cdot \sqrt{1 + 7.9 \cdot \frac{1}{\rho'_{c}} - 2 \cdot \frac{1}{\rho'_{c}} - 1.25} \right)
\]

125.98 MPa = 34.45 MPa \left[ 2.25 \cdot \sqrt{1 + 7.9 \cdot \frac{1}{34.45 - 0.61}} \right] \cdot \left[ \frac{2 \cdot t_{f} \cdot (4 \cdot 10^{-3} \cdot 124.1 \cdot 0.03)}{34.45 \cdot MPa \cdot 0.61 \cdot m} \right] - 2 \cdot \frac{2 \cdot t_{f} \cdot (4 \cdot 10^{-3} \cdot 124.1 \cdot 0.03)}{34.45 \cdot MPa \cdot 0.61 \cdot m} - 1.25 \Rightarrow t_{f} \rightarrow 0.0817 m \quad t_{f} = 81.7 mm

or

\[
t_{f} = 0.02611 m \quad t_{f} = 25.11 mm \quad t_{f} = 1.028 m
\]

Assume given ductility desire is 10:

\[
\rho_{cc} = \rho'_{c} \left( -0.503 \cdot \frac{1}{\rho'_{c}} + 2.775 \cdot \frac{1}{\rho'_{c}} + 0.9469 \right)
\]

105.83 MPa = 34.45 MPa \left[ 0.9469 - 0.503 \cdot \left( \frac{2 \cdot t_{f} \cdot 1310}{610 \cdot 34.45} \right) + 2.775 \cdot \frac{2 \cdot t_{f} \cdot 1310}{610 \cdot 34.45} \right] \Rightarrow t_{f} \rightarrow 36.98 mm

or

\[
t_{f} = 0.289 m
\]

Assume given ductility desire is 10:

\[
\rho_{cc} = \rho'_{c} \left( -0.503 \cdot \frac{1}{\rho'_{c}} + 2.775 \cdot \frac{1}{\rho'_{c}} + 0.9469 \right)
\]

125.98 MPa = 34.45 MPa \left[ 0.9469 - 0.503 \cdot \left( \frac{2 \cdot t_{f} \cdot 1310}{610 \cdot 34.45} \right) + 2.775 \cdot \frac{2 \cdot t_{f} \cdot 1310}{610 \cdot 34.45} \right] \Rightarrow t_{f} \rightarrow 0.0817 m
Seismic Design Using Proposed Strain Model and Girgin’s Strength Model

Assume given ductility desire is 8:

\[
p_{cc} := 105.83 \text{ MPa} \quad \text{From Above Calculations}
\]

\[
p_{cc} = f_i + \sqrt{f_e^2 + 3.5 \cdot f_e \cdot f_i}
\]

\[
105.83 = \frac{2 \cdot t_{f3} \cdot 1310}{610} + \sqrt{34.45^2 + 3.5 \cdot 34.45 \cdot \frac{2 \cdot t_{f3} \cdot 1310}{610}} \quad \text{solve}, t_{f3} \rightarrow 7.8045027223731473711
\]

\[
t_f := 7.80 \text{ mm} \quad t_f = 0.307 \text{ in}
\]

Assume given ductility desire is 10:

\[
p_{cc} := 125.98 \text{ MPa} \quad \text{From Above Calculations}
\]

\[
p_{cc} = f_i + \sqrt{f_e^2 + 3.5 \cdot f_e \cdot f_i}
\]

\[
125.98 = \frac{2 \cdot t_{f3} \cdot 1310}{610} + \sqrt{34.45^2 + 3.5 \cdot 34.45 \cdot \frac{2 \cdot t_{f3} \cdot 1310}{610}} \quad \text{solve}, t_{f3} \rightarrow 10.431875607126321766
\]

\[
t_f := 10.43 \text{ mm} \quad t_f = 0.411 \text{ in}
\]
Seismic Design Using Mander et al's Strain Model and ACI 440 Strength Model

Assume given ductility desire is $\mu_d = 8$

$$\gamma_p = 0.08 \cdot H + 0.022 \cdot \gamma_p \cdot d_b$$  Plastic Hinge Length for Single Bending

$$\gamma_p = 419.5 \text{ mm}$$

$$\mu_p := 1 + \frac{\mu_d - 1}{2 - 0.5 \cdot \frac{\gamma_p}{H}}$$

$$\mu_p = 22.584$$

$$\varepsilon_{cc} = \mu_p \cdot \varepsilon_{fu} \quad \varepsilon_{cc} = 0.0252$$  Confined Concrete Strain

Mander et al's Strain Model:

$$\varepsilon_{cc} = \varepsilon_{cc} \left[ 1 + 5 \cdot \left( \frac{\varepsilon_{cc}}{\varepsilon_c} - 1 \right) \right]$$

$$0.0252 = 0.002 \cdot \left[ 1 + 5 \cdot \left( \frac{\varepsilon_{cc}}{34.45} - 1 \right) \right] \Rightarrow \varepsilon_{cc} = 114.37 \text{ MPa}$$

$$\sigma_{cf} := 114.37 \text{ MPa}$$  Required Confined Strength of Concrete
