PORTABLE FIELD WATER SAMPLE FILTRATION UNIT†

Alvin J. Hebert and Gardener G. Young
Lawrence Berkeley Laboratory
University of California
Berkeley, California 94720

The need for a lightweight back-packable filtration unit that could easily be cleaned without cross-contamination at the part-per-billion level while allowing rapid filtration of boiling hot and sometimes muddy water has given rise to the unit shown in Figure 1.

Filtrations are performed by pouring the solution into the funnel or by placing a piece of tygon tubing down a well and drawing the water up and through the filter. Boiling water has been drawn up old geothermal well pipes as high as 5 meters in this manner. Filtration usually takes less than one or two minutes per 500 ml bottle when the water is not too muddy. During the filtration process, it is important that bubbles not be allowed in the input line, otherwise the unit will cease functioning properly until it is reopened and a new filter inserted.

Field and laboratory tests indicate essentially no changes in carbonic acid or bicarbonate or carbonate ion concentrations when filtrations are performed at approximately 1/3 atmosphere of vacuum even though the pH value may range from 3.2 to 9.4.

The aluminum tubing sleeve shown in Figure 1 on one of the 500 ml. Nalgene bottles guards against bottle collapse when filtering
very hot water. The snap-in nipples for line connections to the lid of the bottle were machined from nylon. Total unit weight without lines or bottles is 3.5 kg.

Figure 2 shows the machined groove pattern of the main body tef­lon plate. These grooves are "round-bottomed" to facilitate cleaning. The tygon lines are connected to this plate via a small nylon nipple and viton O-ring to insure vacuum integrity. Also a large viton O-ring is placed in the outer groove. The 16.5 cm. diameter unit is designed to accept a standard Millipore acetate filter (variety HAWP-142, 0.45 micron, 142 mm plain white filter sheet) which is laid over the groove plate and viton O-ring prior to each clamp down and filtration. No separate filter support is necessary. A 2mm deep recess is machined into the mating top teflon disk shown in Figure 1.

The eight central holes shown in Figure 2 lead to the nylon nipple connector which fits into a mating recess on the other side. The main body teflon plates are backed by 1.27 cm thick aluminum plates.

The hand vacuum pump is manufactured by the Nalgene Labware Division of NALGE Sybron Corporation. The legs on the unit are easily removed for backpacking. The ends of the tie down bolts are expanded so that the brass butterfly nuts will not fall off.
