1. INTRODUCTION

A numerically efficient representation for short-pulse (wideband) field propagation in an environment as in Fig.1a is presented in terms of time-domain (TD) rays. Closed form uniform wavefront approximations of the organized multiple diffracted fields are provided, using simple TD transition functions. Focus is given on an arbitrary nth diffracted mechanism, as shown in Fig.1a, with specialization on a second order diffraction mechanism (doubly diffracted (DD) fields) as in Fig.1b. The uniform asymptotic solutions for singly diffracted (SD) and DD fields are valid for early observation times (wavefront approximations). Their time-range of validity may be extended to late observation times when the exciting signal does not contain low frequency components. Higher order diffracted fields are approximated using an efficient numerical convolution between TD-SD fields. For simplicity we will not consider here hybrid mechanisms, such as reflected-diffracted rays, etc. The response of the total field to an impulsive excitation (Dirac delta function) is represented in terms of ray fields as

$$\hat{\psi}_{nT}(t) = \hat{\psi}_{GO}(t) + \hat{\psi}_{SD}(t) + \hat{\psi}_{DD1}(t) + \hat{\psi}_{DD2}(t) + \ldots$$

(1)

in which $\hat{\psi}_{GO}(t)$ includes all the TD geometrical optics (GO) fields, $\hat{\psi}_{SD}(t)$ includes all the TD-SD fields, $\hat{\psi}_{DD1}(t)$ includes all the TD double diffracted (DD) fields, $\hat{\psi}_{DD2}(t)$ includes all the TD triply diffracted (DD) fields, and so on. When the source radiates a waveform $\mathcal{G}(t)$, the impulsive response (1) is used to construct the total radiated field $\hat{\psi}_{nT}^{\mathcal{G}}(t) = \hat{\psi}_{nT}(t) \otimes \mathcal{G}(t)$, in which $\otimes$ denotes time convolution. Instead of representing the total diffracted field as a continuous superposition (convolution) of impulsive responses, it might be convenient to approximate it as a discrete superpositions of rectangular-pulse responses. Accordingly, the excitation waveform $\mathcal{G}(t)$ is expanded as a superposition of rectangular pulses of duration $T$

$$\mathcal{G}(t) = \sum_{n=1}^{N} g_n \text{rect}(t-nT, T), \quad \text{rect}(t, T) = U(t+\frac{T}{2}) - U(t-\frac{T}{2}), \quad U(t) = \begin{cases} 0 & t < 0 \\ 1 & t \geq 0 \end{cases}$$

(2)

in which the weights $g_n = \mathcal{G}(nT)$ sample the excitation waveform $\mathcal{G}(t)$ in the middle of the rectangular pulses. The total field is thus approximated as

![Fig. 1. (a) Multiple diffracted ray. (b) Double diffracted (DD) ray and notation used in [5]](attachment:image)
\[ \bar{\psi}_{\text{GO}}(t) = \sum_{n=1}^{\infty} \bar{\psi}_{\text{GO}}(t-nT), \quad \bar{\psi}_{\text{GO}} = 2^{1/2} \bar{\psi}_{\text{GO}}, \quad \bar{\psi}_{\text{GO}} = 2^{1/2} \bar{\psi}_{\text{GO}}, \quad \ldots \] (3)

in which the responses to the rectangular pulse, \( \bar{\psi}_{\text{GO}} \), \( \bar{\psi}_{\text{GO}} \), and \( \bar{\psi}_{\text{GO}} \), are evaluated in closed form from the impulse response \( \bar{\psi}_{\text{GO}} \) in Sections II and IV. The present formulation has several advantages. First, the representation (3) of the total radiated field \( \bar{\psi}_{\text{GO}} \) is asymptotically uniform, as it was the total impulsive radiated response (1). Second, the various terms are easier to evaluate than (1), since they do not contain singularities due to the Dirac delta excitation. Indeed, the GO field for rectangular excitation \( \bar{\psi}_{\text{GO}}(t) = \text{rect}(t,T)/(4\pi R) \), with \( R \) the distance between source and observer, is finite and band limited, imposing the same properties when it is multiply diffracted.

II. TIME DOMAIN SINGLE DIFFRACTION (TD-SD)

The impulsive TD-SD field has been presented in [1], [2], [3], while the response to the unit step function \( U(t) \) has been presented in [4]. After expressing the rectangular pulse as \( \text{rect}(t,T) = U(t+T/2) - U(t-T/2) \), the TD-SD field response to a rectangular pulse is obtained as the difference

\[ \bar{\psi}_{\text{SD}}(t-T) = \bar{\psi}_{\text{SD}}(t+T/2) - \bar{\psi}_{\text{SD}}(t-T/2), \quad \bar{\psi}_{\text{SD}}(t) = \frac{1}{\sqrt{\pi T'}} \bar{D}_{\text{TD}}^0(t-t'), \quad (4) \]

in which \( \bar{\psi}_{\text{SD}}(t) \) is the response to the unit step function \( U(t) \) from [4], or obtained by integrating the results in [1], [2], [3]. \( T' = (r+r')/c \) is the turn-on time (wavefront arrival time) of the diffracted field, and

\[ \bar{D}_{\text{TD}}(t-t') = \frac{1}{2\sqrt{2\pi \sin \theta_0}} \sum_{m=1}^{N} \bar{D}_{\text{TD}}(x_m,t-t') \] (5)

is the TD-SD diffraction coefficient. The TD transition function

\[ f^T(x_m,t) = 2 \sqrt{\frac{x_m}{\pi \sin \theta_0}} \arctan \left( \frac{t-x_m}{c} \right) U(t) \] (6)

is evaluated from the convolution \( f^T(x_m,t) = f(x_m,t) * U(t) \) where \( f(x_m,t) = x_m/\sqrt{\pi \sin \theta_0} \), in which \( f(x_m,t) \) is the transition function for impulsive excitation (we have used the notation in [3]). The parameters in (5) are \( d_{m}^n = \cot(\pi - (1-1)^m (\phi - \phi'))/(2n) \), for \( m = 1, 2, \ldots \), \( d_{m}^n = \cot(\pi - ((1-1)^m (\phi + \phi'))/(2n) \), for \( m = 3, 4 \), \( z_1 = 2L \cos^2(2\pi n N - (\phi + \phi'))/2, \quad z_2 = 2L \cos^2(2\pi n N - (\phi - \phi'))/2, \quad z_3 = 2L \cos^2(2\pi n N - (\phi + \phi'))/2, \quad z_4 = 2L \cos^2(2\pi n N - (\phi - \phi'))/2, \)

\[ \quad \text{where } L = \frac{r+r'}{(r+r')} \text{ for spherical wave incidence}, \quad N^* \text{ are the integers that most nearly satisfy the equation } 2\pi n N^* - (\alpha + \alpha') = \pm \pi, \quad \phi' \text{ is the incidence angle}, \quad r' \text{ is the incidence distance}, \quad \phi \text{ is the observation angle}, \quad r \text{ is the observation distance and } n \text{ is the wedge aperture angle factor.}

III. TD MULTIPLE DIFFRACTIONS

Multiple diffractions may be computed by cascading TD-SD fields derived in the previous section. Let \( P_0 \) be the source, \( P_{N+1} \) the observation, and \( P_1, P_2, \ldots, P_N \) the locations of \( N \) diffraction points (see Fig.1a), a pulsed field emitted at \( P_0 \) produces a transient field at \( P_{N+1} \) computed repeating \( N \) times the following steps:

1. Evaluate the field \( \psi^T_{i-1}(P_{i-1},t) \) incident on \( P_i \), due to the source \( P_{i-1} \).
2. Approximate the incident field \( \psi^T_{i-1}(P_{i-1},t) \) as

\[ \psi^T_{i-1}(P_{i-1},t) = \sum_{n=1}^{N} \psi^T_{i-1}(P_{i-1},nT) \text{rect}(t-nT,T) \] (7)
and note that the field $\psi^d_{t-1}(P_i, t)$ is sampled at the center of the rectangles $(P_{i+1}, n_T)$.  

3. Using the previous incident field $\psi^d_{t-1}$ evaluate at $P_{i+1}$ the field diffracted at $P_{i+1}$ 

\[ \psi^d_{t-1}(P_{i+1}, t) \approx \sum_{n=1}^{N} \psi^d_{t-1}(P_{i+1}, n_T) \frac{\partial^*}{\partial t^*}(P_{i+1}, t) \]  

in which the diffracted field $\psi^d_{t-1}(P_{i+1}, t)$ is the response to the rectangular pulse excitation (4).

In evaluating the field multiply diffracted by wedges, two peculiar situations may occur: a) two consecutive edges have a common face and the electric field is tangent to the common face (soft polarization); b) two consecutive edges are experiencing a double transition, i.e., two consecutive diffraction points $P_i$ and $P_{i+1}$ are almost aligned with source $P_i-1$ and observer $P_{i+1}$. In such cases, more accurate results are accomplished by introducing a TD version of the double diffraction mechanism that is discussed in the next section.

IV. TIME DOMAIN DOUBLE DIFFRACTION (TD-DD)

The TD response of a double wedge to a rectangular pulse is derived from the uniform wavefront approximation for the impulsive TD-DD field presented in [5], [6]. Similarly to the SD case (4), the TD-DD field response is obtained as the difference

\[ \psi^{dd, U}(t - T) = \psi^{dd, U}(t + T/2) - \psi^{dd, U}(t - T/2) \]  

where $\psi^{dd, U}$ is the response to a unit step function. Referring to Fig. 1b, the TD-DD field is given by $\psi^{dd, U} = A^* A^t - \psi^{dd, U} A^t A^*$, where $A^*$ is the incident spreading factor [for a spherical source, $A^s(r_i) = 1/(4\pi r_i^2)$] at $P_i$, $A^t(r_{i+1}, t) = \sqrt{r_{i+1}^2 + t + r_i}$ is the DD field spreading factor. $B_d^U(t - T/2)$ is the TD-DD coefficient, evaluated at the retarded time $t - T/2$, where $t^d = (r_i + t + r_i)/c$ is the turn-on time of the DD field. Similarly to the frequency domain case [5], [7], the double diffraction coefficient is $B_d^U = B_d^U + B_d^H$, with

\[ B_d^U(t) = \sum_{p, r, s=1}^{2} \frac{\delta_{p} \delta_{s} \delta_{r} \delta_{t}}{\sin B_1 \sin B_2} \frac{\partial^*}{\partial t^*}(a_{pq}, b_{rs}, w, t) \]  

\[ B_d^H(t) = \sum_{p, r, s=1}^{2} \frac{\delta_{p} \delta_{s} \delta_{r} \delta_{t}}{\sin B_1 \sin B_2} \frac{\partial^*}{\partial t^*}(a_{pq}, b_{rs}, w, t) \]  

where upper/lower sign applies to the soft/hard case, respectively. The TD-DD transition functions

\[ P_{1,2}(a, b, w, t) = \left\{ \begin{array}{ll}
\frac{a b}{2ab/w} & \text{if } a \neq 0 \text{ and } b \neq 0 \ni \sqrt{1 - w^2} \\
G \left( \frac{a + w b}{\sqrt{1 - w^2}}, t \right) + G \left( \frac{a - w b}{\sqrt{1 - w^2}}, t \right) & \text{if } a = 0 \text{ or } b = 0 \\
G \left( \frac{a + w b}{\sqrt{1 - w^2}}, t \right) & \text{if } a > 0 \text{ and } b > 0 \\
G \left( \frac{a - w b}{\sqrt{1 - w^2}}, t \right) & \text{if } a < 0 \text{ and } b < 0 
\end{array} \right. \]  

are obtained by the convolution $P_{1,2}(a, b, w, t) = P_{1,2}(a, b, w) * U(t)$, $P_{1,2}(a, b, w)$ being the transition functions for TD-DD field with impulsive excitation [5], [6], that is calculated in closed form as of $G(x, y, t) = \{ \arctan \left( \frac{x}{y} \sqrt{1 + t^2} \right) - \arctan \left( \frac{x}{y} \right) \} U(t)$. The various parameters are defined as in [5], [6], $a_{pq} = \sqrt{r_{i+1}^2 + t + r_i}$, $b_{rs} = \sqrt{r_{i+1}^2 + t + r_i}$, $h_{pq} = \sqrt{r_{i+1}^2 + t + r_i}$, $h_{rs} = \sqrt{r_{i+1}^2 + t + r_i}$, $\delta_{p} = \delta_{s} = 2\pi n_{pq}$ for $\Phi^p = 2\pi n_{pq}$, $\delta_{r} = \delta_{t} = 2\pi n_{rs}$ for $\Phi^r = 2\pi n_{rs}$, in which $\Phi^p$ and $\Phi^r$ are the integers that most nearly satisfy $\Phi^p = 2\pi n_{pq}$ and $\Phi^r = 2\pi n_{rs}$, respectively; being $\Phi^p = \pi + (-1)^{\lambda_{pq}} \Phi_{pq}$ and $\Phi^r = \pi + (-1)^{\lambda_{rs}} \Phi_{rs}$. Furthermore $\Phi_{pq} = \pi + (-1)^{\lambda_{pq}} \phi_{pq}$ and $\Phi_{rs} = \pi + (-1)^{\lambda_{rs}} \phi_{rs}$. The second order contribution $B_d^H(t)$ becomes particularly important in two possible cases: when two edges have a common face, and when source and observation are almost aligned with two consecutive edges.
V. NUMERICAL EXAMPLES AND CONCLUSIONS

Numerical results for the diffraction of a rectangular pulse by the double wedge of Fig. 1b are shown in Fig. 2. The different ray segments are assumed to be \( r_1 = 42 \text{cm} \), \( r_2 = 33 \text{cm} \), and \( r_3 = 45 \text{cm} \), while the involved angles are \( \beta_1 = \beta_2 = 100^\circ, \beta_3 = 250^\circ \), \( \phi_1 = 250^\circ \). Three cases are considered. In the first case both incidence on the first edge and observation w.r.t. the second edge are out of transition \( \phi = 320^\circ \). In the second case observation is taken at its transition aspect, that is at grazing \( \phi = 260^\circ \), while the incidence is still out of transition \( \phi = 320^\circ \). The last case considers both incidence and observation at grazing \( \phi = \phi_2 = 260^\circ \), thereby DD experiences a double transition.

The response to a \( T = 50 \text{ps} \) rectangular pulse was computed in two different ways: 1) by cascading the single diffraction mechanism as explained in Sections II and III (dashed black line); and 2) by using the double diffraction mechanism of Section IV (continuous gray line). These results show that there is strong agreement between the responses obtained with the two methods outside the transition zone; the agreement is still very good when only one aspect is in transition, but greater differences are observed when a double transition occurs. The diffraction of the pulse \( \cos(2\pi ft)\text{rect}(t) \), which contains mostly high frequency components, by the four consecutive edges of Fig. 1a is reported in Fig. 3. The duration of the pulse is \( T = 20 \text{ns} \), the carrier frequency \( f = 1 \text{GHz} \), the sampling interval \( \Delta t = 0.25 \text{ns} \) and the polarization is soft. The geometrical parameters for this example are \( r_1 = 1 \text{m}, r_2 = 3 \text{m}, r_3 = 5 \text{m}, \phi_1 = 81^\circ, \phi_2 = 260^\circ, \phi_3 = 281^\circ, \phi_4 = 80^\circ \).

In conclusion, numerically efficient results for short pulse propagation in a complex environment have been presented in terms of multiple diffraction. Our TD diffraction propagators are based on discretization of a generic short-pulse in terms of narrow rectangles, and on closed form representations of diffracted fields when the excitation is a narrow rectangular pulse.
