ABSTRACT

We have studied the Dalitz plot for the recently observed charged
state decaying into $K^+\pi^+\pi^-$ at 1876 MeV/c^2 and we find that the final
state is incompatible with a natural spin parity assignment. This informa-
tion, coupled with the earlier observation of the $K^+\pi^-$ decay mode (a
final state of natural spin parity) of the neutral state at 1865 MeV/c^2,
suggests parity violation in the decays of these objects if they are mem-
bers of the same isomultiplet as their proximity in mass suggests.

We have recently reported our observation in $e^+e^-$ annihilation of a narrow, charged state of mass 1876 MeV/$c^2$ decaying into the exotic decay mode $K^\pm \pi^\mp \pi^\pm$. The proximity in mass of this state to the neutral state decaying into $K\pi$ and $K3\pi$ at 1865 MeV/$c^2$ suggests that they are members of the same isomultiplet, and so they are expected to have the same parity. Since the $K\pi$ final state has natural spin parity, a demonstration that the $K\pi\pi$ final state of the charged member of the isomultiplet is inconsistent with natural spin parity implies a parity violation in the decay. In this Letter we present evidence, based on a study of the $K^\pm \pi^\mp \pi^\pm$ Dalitz plot for such a parity violation, suggesting that the decay proceeds via the weak interaction as expected for the predicted $(D^+, D^0)$ isodoublet of charm.

The present analysis is based on $K\pi\pi$ events observed among a sample of ~44,000 hadronic events taken from 3.9 GeV to 4.25 GeV center-of-mass energy. These data were taken with the SLAC-LBL magnetic detector at SPEAR.

The $K\pi\pi$ combinations are selected with the aid of the time-of-flight system described in Ref. 2. In the present analysis we have used a modified form of the time-of-flight (TOF) weighting technique described earlier. A given track in a multi-prong hadronic event is assigned a definite particle identity on the basis of the agreement between its observed TOF over a 1.5 - 2.0 meter flight path and that predicted for either a $\pi$ or a $K$ with a momentum as measured. Specifically we compute a $x^2$ value for both the $\pi$ and $K$ hypotheses ($x^2_\pi$ and $x^2_K$) based on the observed and expected TOF and the 0.4 ns rms resolution of the TOF system. Tracks satisfying the requirements $x^2_K < x^2_\pi$, $x^2_K < 3$ are called kaons. Protons and antiprotons are separated from
kaons in a similar fashion. The remaining tracks are called pions.\textsuperscript{4} The above technique allows the direct study of scatter plots and in particular the Dalitz plot for the $K\pi\pi$ system.

In order to obtain a relatively clean sample of $K\pi(1876)$ events we make use of the result that for the $E_{cm}$ region, $3.9 < E_{cm} < 4.25$ GeV; the recoil mass ($M_{rec}$) spectrum shows a sharp spike near 2 GeV.\textsuperscript{1} We thus used a data sample with the $E_{cm}$ region chosen as above coupled with a cut $1.96 < M_{rec} < 2.04$ GeV/c\textsuperscript{2}. Figure 1a and 1b show the resulting exotic and nonexotic $K\pi\pi$ invariant mass distributions. A fit to the spectrum of Fig. 1b was appropriately scaled to serve as a background for Fig. 1a, which shows a fit to a Gaussian peak over this background. Figure 2a shows the (folded) Dalitz plot for $K^{\pm}\pi^{\mp}\pi^{\mp}$ events with the additional invariant mass ($M$) requirement $1.86 < M < 1.92$ GeV/c\textsuperscript{2}. We find a sample of 126 events in the Dalitz plot of Figure 2a of which we estimate 58 are background. In Figure 2b we show a background Dalitz plot consisting of 112 nonexotic combinations $K^{\pm}\pi^{\mp}\pi^{-}$ satisfying the same mass and missing mass cuts as the exotic combinations of Figure 2a.

Both signal and background Dalitz plots are consistent with uniform population density. A uniformly populated Dalitz plot is incompatible with a $K\pi\pi$ final state of pure, natural spin parity.\textsuperscript{5} For the case of a natural spin-parity state decaying into three pseudoscalars one expects a depopulation (or zero) along the Dalitz plot boundary. This follows from the necessity of constructing the matrix element from the vector product of the two independent center-of-mass momenta—a vector which vanishes on the Dalitz plot boundary where momenta are collinear. If, as in the case of $K^{\pm}\pi^{\mp}\pi^{\mp}$, two of the pseudoscalars are identical, one expects additional zeros. Since three
pseudoscalars cannot be in a $0^+$ spin parity state, $1^-$ and $2^+$ exhaust natural
spin parity combinations for spin less than 3. For the case of $1^-$ one
expects an additional zero along the $y$-axis (symmetry axis), while in the
case of $2^+$ one expects a higher order zero at the top of the Dalitz plot.

In order to quantitatively rule out the $K\pi\pi$ final states of $1^-$ and $2^+$
we have utilized the phenomenological matrix elements of Zemach. These are
the simplest matrix elements and are subject to multiplication by arbitrary
form factors. Barring the presence of rapidly varying form factors, they can
be expected to give a good approximation to the extent of the regions of
depopulation, allowing a quantitative comparison with the experimental
distribution.

For $J^P = 1^-$ the matrix element is constructed from an axial vector symmetric
under the exchange of the two pions. The essential form of such a quantity
is $(T_{\pi_1} - T_{\pi_2})\vec{\pi}_1 \times \vec{\pi}_2$, where $\vec{\pi}$ represents a pion momentum in the rest frame of
the $K\pi\pi(1876)$, and $T_{\pi}$ represents its kinetic energy. For the case of unpolarized
production one then expects an intensity $I_{1^-}$ given by

$$I_{1^-} \propto |T_{\pi_1} - T_{\pi_2}|^2 |\vec{\pi}_1 \times \vec{\pi}_2|^2.$$  

To compare the distribution of $I_{1^-}$ with the data, we have divided the
Dalitz plot into two discrimination regions divided by a contour of constant
$I_{1^-}$. The particular contour was chosen so that an equal number of events would
be found in each region for a phase space decay of the state $K\pi\pi(1876)$, as
determined by a Monte-Carlo calculation. Owing to the approximately uniform
$K\pi\pi$ detection efficiency over the Dalitz plot these regions have nearly equal areas.
Figures 3a and 3b show the $K\pi^+\pi^+$ invariant mass spectra for events with
Dalitz variables lying inside the two $l^-$ discrimination regions as indicated by the shaded area in the respective inserts.

A fit to a Gaussian signal over the scaled background of Fig. 1b reveals $34 \pm 8$ signal events in the peripheral region compared to $38 \pm 9$ signal events in the central region. Such a division is consistent with equal population with a $\chi^2$ of 0.1 for one degree of freedom (DF) or a confidence level $CL = 75\%$.

On the other hand, a Monte-Carlo simulation of $K\pi\pi$ decays using the intensity distribution $I_1$ gives an expected population division of 1:8.2 for peripheral to central region. This is effectively ruled out with a $\chi^2$ of 18.1 ($CL = 2 \times 10^{-5}$).

For $2^+$ we construct a symmetric, traceless, second-rank tensor which is also symmetric under the exchange of the two pions. We use $A_{ij} = \Delta\pi^i q^j + \Delta\pi^j q^i$ where $\Delta\pi$ is the difference of the pion momenta and $q$ is their cross product.

For unpolarized production one expects an intensity given by:

$$I_{2^+} = \sum_i \sum_j A_{ij} A_{ji} = |\vec{\pi}_1 - \vec{\pi}_2|^2 |\vec{\pi}_1 \times \vec{\pi}_2|^2.$$ 

Here we again divide the Dalitz plot into two regions, using a contour of constant $I_{2^+}$ chosen to give equal population for phase space decay. $I_{2^+}$ depopulates the peripheral region relative to the central region by 1:5.6.

Figure 5b and 3c show the $K^{\pm}\pi^{\mp}\pi^\pm$ invariant mass spectra for events with Dalitz variables in the shaded $2^+$ discrimination regions. Our fits give $31 \pm 9$ events in the peripheral regions and $35 \pm 10$ events in the central region. This result is again consistent with equal population with a $\chi^2$ of 0.1 for one DF ($CL = 75\%$), and inconsistent with $I_{2^+}$ with a $\chi^2$ of 9.4 for one DF ($CL = 0.002$). The observed sample population of the $2^+$ peripheral discrimination region indicates the absence of a general boundary zero.
absence of such a zero argues against natural spin parity final states of spin 3 and greater as well.

In summary the distribution in the Dalitz plot is incompatible with the zeros expected for spin parity $1^-$ or $2^+$ for the $K\pi\pi(1876)$. Parity violation then follows from the observation that the presumed isomultiplet state at 1865 MeV/c$^2$ decays into $K\pi$, a natural spin parity state.

We wish to thank W. Chinowsky for useful discussions.
