A 32-year-old female presented to the emergency department after a motor vehicle collision with complaints of thoracic back pain. Further history was not obtainable owing to marked ethanol intoxication. Vital signs and physical examination were unremarkable except for a mild tachycardia, which resolved with intravenous fluids. A chest radiograph was obtained (Figure 1). Medical records’ review revealed that the same abnormality had been noted 17 months earlier (Figure 2).

**DIAGNOSIS**

Most pericardial cysts are congenital, forming during embryogenesis from a persistent parietal recess. They are uncommon, with an estimated prevalence of 1 in 100,000 population. Approximately 1 in 6 patients are symptomatic with complaints of chest pain or dyspnea. Pericardial cysts may cause cardiac compression and may enlarge over time. They are easily seen on routine chest radiographs and may be an incidental finding as in our case. Diagnosis is confirmed by the absence of other causes of chest pain or dyspnea so that patients can be discharged home with reassurance.

**Figure 1.** Supine anteroposterior chest radiograph showing (arrow) a 6 × 8-cm focal mass in the left lung base.

**Figure 2.** Chest computed tomographic scan with intravenous contrast obtained 17 months previously and showing (arrow) a 4.5 × 2.8-cm, well-defined, encapsulated fluid collection contiguous with the left heart border.
with computed tomography or magnetic resonance imaging, and surgical treatment is indicated for symptomatic patients. 1,2 Watchful observation may be feasible for asymptomatic patients, but outcome data are lacking and thus preventive resection may be preferred. 2
