In order to allow quantitative interpretation of the reactions of high energy particles from the 184-inch cyclotron with tantalum and heavier elements, a systematic survey is being made of radioactive isotopes of the rare earth elements; hafnium, tantalum, tungsten and rhenium. Bombardments of various elements are being made using 38 Mev and 20 Mev helium ions, 19 Mev deuterons and 10 Mev protons from the 60-inch Crocker Laboratory cyclotron. Chemical separation of the rare earth elements is made by ion-exchange resin columns. The accompanying table summarizes present data; energies of radiations are determined from absorption measurements; positrons are observed using a "magnetic counter"; mass allocations are made on the basis of measured cross-sections.

Detailed accounts of experimental techniques and of the isotopes will be published.

The allocation of the previously reported 6 active isotopes of lutecium with half-lives of 3.75 h and 6.8 d, to masses 176 and 177 respectively, has been confirmed by measurement of the d,p cross sections for 19 Mev deuterons on lutecium.

This paper is based on work carried out at the University of California under the auspices of the Atomic Energy Commission.
