Venugopal SK, Jiang J, Kim T-H, Li Y, Wang S-S, Torok NJ, Wu J, Zern MA. Liver fibrosis causes downregulation of miRNA-150 and miRNA-194 in hepatic stellate cells, and their overexpression causes decreased stellate cell activation. Am J Physiol Gastrointest Liver Physiol 298: G101–G106, 2010. First published November 5, 2009; doi:10.1152/ajpgi.00220.2009.—Activation of hepatic stellate cells (HSC) results in their proliferation and in the secretion of extracellular matrix (ECM) proteins, which leads to hepatic fibrosis. microRNAs (miRNAs) have been shown to regulate various cell functions, such as proliferation, differentiation, and apoptosis. Hence, we have analyzed the miRNAs that were differentially expressed in HSC isolated from sham-operated and bile duct-ligated rats. Expression of two miRNAs, miRNA-150 and miRNA-194, was reduced in HSC isolated from fibrotic rats compared with sham-operated animals. These two miRNAs were overexpressed in LX-2 cells, and their ability to inhibit cell proliferation, the expression of smooth muscle α-actin (SMA), a marker for activation, and collagen type I, a marker for ECM secretion, was determined. Overexpression of these two miRNAs resulted in a significant inhibition of proliferation (P < 0.05) and reduced SMA and collagen I levels compared with either untreated cells or nonspecific miRNA-expressing cells. Next, the protein targets of these two miRNAs were found using bioinformatics approaches. C-myb was found to be a target for miRNA-150, and rac 1 was found to be one of the targets for miRNA-194. Therefore, we studied the expression of these two proteins by overexpressing these two miRNAs in LX-2 cells and found that overexpression of miRNA-150 and miRNA-194 resulted in a significant inhibition of c-myb and rac 1 expression, respectively. We conclude that both miRNA-150 and miRNA-194 inhibit HSC activation and ECM production, at least in part, via inhibition of c-myb and rac 1 expression.

THE DEVELOPMENT OF HEPATIC FIBROSIS is a result of a wound-healing response attributable to liver injury. Hepatic stellate cells (HSC) are the major cell type responsible for the progression of liver fibrosis. These cells reside in the space of Disse and store vitamin A in lipid droplets. Upon liver injury, they lose these droplets, proliferate, and differentiate into myofibroblast-like cells (22). The activated HSC undergo continuous proliferation and express activation markers such as smooth muscle α-actin (SMA) and plasminogen activator inhibitor-1.

Several reports have shown that expression of matrix metalloproteinase (MMP)-1 is inhibited and that tissue inhibitor of metalloproteinase (TIMP)-1 expression is upregulated, resulting in an imbalance between MMP-1 and TIMP-1 and a net increase in extracellular matrix (ECM) accumulation during hepatic fibrosis (3). Several profibrogenic cytokines mediate effects via the activation of the signaling molecules such as c-myb and rac 1 (6, 7). Expression of all these genes is tightly regulated at different levels during hepatic fibrogenesis. We hypothesized that one of the regulatory mechanisms could be through miRNAs (miRNAs).

miRNAs are endogenous, small, noncoding 21–23-nucleotide RNAs that regulate gene expression by binding to the 3′ untranslated region (3′UTR) of the target gene miRNAs to repress translation or induce mRNA cleavage. Thus they play an important role in regulating various cell functions such as development, cell proliferation, differentiation, and apoptosis (4). Increasing evidence suggests that certain miRNAs may contribute to the maintenance of hepatocyte function (18). A recent study has shown that the miRNA-30 family is required for vertebrate hepatobiliary development (9). miRNA-122a has been shown to enhance hepatitis C viral replication in hepatocytes (10). Overexpression of miRNA-27a and 27b was shown to influence fat accumulation and cell proliferation during HSC activation (12). Although emerging evidence suggests a role of miRNAs in affecting liver function, there is a paucity of data on the role of miRNAs in hepatic fibrosis.

In this study, we have determined the differential expression of miRNAs in HSC isolated from both sham-operated and bile duct-ligated (BDL) rat livers. We selected two miRNAs, miRNA-150 and miRNA-194, whose expression was inhibited in HSC isolated from fibrotic livers. These miRNAs were overexpressed in an activated human HSC cell line, LX-2, and their roles in inhibiting proliferation, activation, and ECM production were determined.

MATERIALS AND METHODS

Animals, BDL, and HSC isolation. Male Sprague-Dawley rats from Charles River Laboratories (Wilmington, MA) were used for BDL and HSC isolation. The animals were housed in facilities approved by the National Institutes of Health. All procedures were reviewed and approved by the Animal Welfare Committee of the University of California Davis. The BDL procedure was performed as described previously (13). Primary rat HSC were isolated from both sham-operated and BDL rats as previously described (13, 25) and used 3
miRNA-150 and miRNA-194 inhibit stellate cell activation

Bile duct ligation (BDL) causes the differential expression of microRNAs (miRNA, miR) in hepatic stellate cells (HSC). Liver fibrosis was induced by BDL in male Sprague-Dawley rats. The HSC were isolated and cultured for 3 days, and the miRNA microarray was performed. miRNAs were upregulated (left) or downregulated (right) in HSC isolated from BDL rats compared with sham-operated rats (n = 3; *P < 0.05; **P < 0.01).

**Fig. 1.** Bile duct ligation (BDL) causes the differential expression of microRNAs (miRNA, miR) in hepatic stellate cells (HSC). Liver fibrosis was induced by BDL in male Sprague-Dawley rats. The HSC were isolated and cultured for 3 days, and the miRNA microarray was performed. miRNAs were upregulated (left) or downregulated (right) in HSC isolated from BDL rats compared with sham-operated rats (n = 3; *P < 0.05; **P < 0.01).
autofluorescence of vitamin A droplets, and purity of the HSC from BDL rats was assessed by SMA expression. The purity of the isolated HSC was 95% or greater. The HSC were cultured for 3 days, and then differential expression of the miRNAs was determined by microarray analysis in HSC isolated from BDL rats compared with normal rats (Fig. 1). There was a significant increase in some of the let 7 family members such as let 7a, let 7b, and let 7c, whereas there was a significant decrease in miRNA-150, miRNA-194, miRNA-187, and miRNA-207 in HSC isolated from BDL rats. We hypothesized that the miRNAs that were inhibited in HSC isolated from BDL rats might play a role in inhibiting HSC activation and proliferation. On the basis of the bioinformatics approaches, we found that c-myb was a target for miRNA-150 and rac 1 for miRNA-194. Hence, we selected these two miRNAs for further experiments.

miRNA-150 and miRNA-194 expression was confirmed by the SLqRT-PCR technique using rnu-43 as an internal control. The results showed that there was a significant decrease in the expression of both miRNAs in HSC isolated from the BDL group compared with HSC isolated from the sham-operated control group (Fig. 2).

Overexpression of miRNA-150 and miRNA-194 causes inhibition of LX-2 proliferation. The roles of these two miRNAs in modulating HSC proliferation and apoptosis were studied. An activated human hepatic cell line, LX-2, was selected for all the transfection experiments. Four groups of treatments were used, 1) untreated cells, 2) cells transfected with a NS-miRNA, an miRNA that has been shown not to inhibit any of the known miRNAs, 3) cells transfected with miRNA-150, and 4) cells transfected with miRNA-194. The cells were analyzed 72 h after transfection for proliferation using the WST-1 reagent. There was a 31% and 27% reduction of proliferation (n = 5, P < 0.05) in LX-2 cells transfected with miRNA-150 and miRNA-194, respectively (Fig. 3A). Next, their effect on induction of apoptosis was measured using the TUNEL assay (Fig. 3B). The number of apoptotic nuclei and the total number of cells were recorded in at least 10 different high-power fields. The percentage of apoptotic cells was calculated from five different experiments. There was no significant increase in apoptosis in the miRNA-transfected cells (Fig. 3C). These results indicate that, although these miRNAs could inhibit LX-2 cell proliferation, they did not influence cell survival.

Overexpression of miRNA-150 and miRNA-194 inhibits SMA and collagen-I expression. Next, the effects of overexpression of miRNA-150 and miRNA-194 on HSC activation and ECM protein production were evaluated. SMA is one of

![Fig. 2. Stem-loop, real-time RT-PCR (SLqRT-PCR) of the HSC from BDL and sham-operated control rats. The purified miRNA isolated from HSC was used for SLqRT-PCR as described in MATERIALS AND METHODS. The results confirmed that both miRNA-150 and miRNA-194 were significantly decreased in HSC isolated from the BDL group compared with the sham-operated control group (n = 3 in triplicates; *P < 0.001).](image)

![Fig. 3. Overexpression of miRNA-150 and miRNA-194 inhibits the proliferation of LX-2 cells. The activated human HSC line, LX-2, was cultured and treated in 4 groups, namely untreated cells (i), nonspecific (NS)-miRNA transfected cells (ii), miRNA-150-transfected cells (iii), and miRNA-194-transfected cells (iv). A: cells were incubated with the WST-1 reagent, and the proliferation assay was performed (n = 5; *P < 0.05). B: cells were stained for the induction of apoptosis using the terminal deoxynucleotidyl transferase dUTP-mediated nick-end labeling (TUNEL) assay kit. C: TUNEL-positive nuclei and the total number of cells were evaluated in at least 10 different high-power fields, and the percents of apoptosis were calculated from 5 different experiments.](image)
the markers of stellate cell activation, and it is expressed at high levels in LX-2 cells. Hence, the expression of SMA was analyzed, and we determined that overexpression of either of these two miRNAs resulted in a significant decrease in SMA levels compared with NS-miRNA-transfected or untreated cells, as determined by Western blots (Fig. 4A). The densitometry analysis of these Western blots showed that there was a significant inhibition of SMA expression in the miRNA-transfected cells (36.3 ± 2.7% and 22.1 ± 5.2% inhibition with miRNA-150 and miRNA-194, respectively; Fig. 4B). The immunocytochemical staining further verified the findings (42.3 ± 3.1% and 34.1 ± 7.5% inhibition with miRNA-150 and miRNA-194, respectively; Fig. 4C). Collagen-I is the major ECM protein produced by the activated HSC. Hence, the effect of overexpression of these two miRNAs on the expression of collagen-I protein expression was also studied. Western blot analysis showed that the basal level of intracellular collagen-I levels in the cell lysates was not changed significantly but showed a trend toward being decreased (Fig. 4A, A and B), whereas the collagen-I in the spent media was significantly less in the miRNA-transfected cells as measured by ELISA (P < 0.05) (Fig. 4D).

Overexpression of miRNA-150 and miRNA-194 inhibits c-myb and rac 1 expression in LX-2 cells. On the basis of bioinformatics approaches using the Targetscan 4.1 and Sanger’s database, c-myb was identified as a target gene of miRNA-150, and rac 1 was identified as one of the targets for miRNA-194 (Fig. 5). First, the effect of the miRNAs on c-myb and rac 1 mRNA expression was analyzed using qRT-PCR. The results showed that there was a significant inhibition of c-myb mRNA expression in miRNA-150-overexpressing cells but not in miRNA-194- or NS-miRNA-expressing cells (Fig. 6A). Overexpression of miRNA-194 did not result in significant change in rac 1 mRNA levels (Fig. 6A). Next, the protein expression levels of both c-myb and rac 1 were analyzed using Western blots. β-Actin was used as an internal control in all Western blots. Overexpression of miRNA-150 resulted in a significant inhibition of intracellular protein expression of c-myb, confirming the qRT-PCR results.
G105 miRNA-150 AND miRNA-194 INHIBIT STELLATE CELL ACTIVATION

Fig. 6. Effect of overexpression of miRNA-150 and miRNA-194 on the intracellular expression of c-myb and rac 1 in LX-2 cells. LX-2 cells were cultured and transfected with NS-miRNA, miRNA-150, or miRNA-194. A: cells were collected, total RNA was isolated, and the first-strand cDNA was synthesized, followed by SYBRgreen qRT-PCR amplification for c-myb, rac 1, and GAPDH. The relative expression of c-myb and rac 1 was compared with GAPDH expression (n = 3, *P < 0.05). B: total cellular protein was isolated, and equal amounts of protein were used to detect the intracellular expression of c-myb, rac 1, and β-actin by Western blots. This is representative of 3 experiments. Lane 1, untreated cells; lane 2, NS-miRNA-transfected cells; lane 3, miRNA-150-transfected cells; lane 4, miRNA-194-transfected cells. C: Western blot results from 3 experiments were quantified using densitometry analysis (n = 3, *P < 0.05).

We postulated that the miRNAs that are inhibited in the HSC isolated from BDL rats might play a role in inhibiting the activation of HSC. Using bioinformatics approaches, we determined the predicted target proteins for all the differentially expressed miRNAs in HSC from BDL rats. We found that, for the downregulated miRNA-150, one of the target proteins was c-myb, whereas, for miRNA-194, it was rac 1. Because these proteins play an essential role in liver fibrosis, we focused on these two miRNAs. LX-2 cells were selected for all the transfection experiments because of the following reasons: 1) they are highly activated and are similar to activated primary HSC; 2) these cells express high levels of SMA and collagen-I; and 3) 100% transfection efficiency can be achieved in these cells compared with a much lower percentage in primary HSC. The overexpression of miRNA-150 and miRNA-194 in LX-2 cells resulted in a significant inhibition of proliferation without affecting apoptosis.

During liver fibrogenesis, the expression of MMP-1 is suppressed (17) and TIMP-1 expression is stimulated (11). Because of this imbalance, there is an increased accumulation of collagen-I deposition in the space of Disse. Hence, we studied the overexpression of these two miRNAs on the expression of collagen-I, one of the major types of ECM secreted by HSC. Our data showed that there was a significant decrease in collagen-I in the media from the miRNA (-150 and -194)-transfected cells. Although there was a trend toward less intracellular collagen in the miRNA-transfected cells, the significant decrease was in the collagen in the media. The mechanism of this decrease is not clear. This decrease could be a result of increased degradation of collagen-I attributable to changes in MMP-1 and TIMP-1. Moreover, the activation of HSC results in increased levels of SMA. We analyzed SMA expression and found that the SMA protein levels were significantly decreased in both miRNA-150- and miRNA-194-overexpressing cells. The results demonstrate that these two miRNAs are involved in the inhibition of HSC proliferation, activation, and collagen deposition but did not affect apoptosis.

C-myb is a protooncogene that encodes a transcription factor involved in proliferation, differentiation, and survival of hematopoietic cells (19). There are reports showing that activated HSC also express c-myb and that its expression contributes to the development of fibrosis in animal models (14). In addition,
oxidative stress has been shown to induce both collagen-I and SMA via c-myb in rat HSC (15). Rac 1, a member of the Rho family of small GTP-binding proteins, promotes proliferation and migration by activating the membrane-associated NADPH oxidase complex to produce superoxide anion, a signaling molecule involved in these processes. Various studies have shown that both reactive oxygen species and rac 1 are required for HSC proliferation and activation (8, 21). LX-2 cells express both c-myb and rac 1 constitutively. A recent study has shown that c-myb is targeted by miRNA-150 in breast cancer cells (16). Hence, we determined the role of miRNA-150 on c-myb expression and miRNA-194 on rac 1 expression in LX-2 cells. In agreement with the previous report (16), in our system miRNA-150 overexpression also resulted in decreased levels of c-myb mRNA and decreased c-myb protein expression. When the LX-2 cells were transfected with miRNA-194, there was no significant difference in rac 1 mRNA levels; however, the level of rac 1 protein was significantly inhibited, suggesting that the inhibition might be at a translational level.

In summary, our results suggest that two specific miRNAs (miRNA-150 and miRNA-194) might play a critical role in hepatic fibrogenesis. It appears that miRNA-150 and miRNA-194 might play a critical role in the regulation of hepatic fibrosis. It appears that miRNA-150 and miRNA-194 might play a critical role in the inhibition might be at a translational level.
