EU support reductions would benefit California tomato growers and processors

by Bradley J. Rickard and Daniel A. Sumner

Many countries apply import barriers for processing tomatoes, but the European Union is the main producer that uses export and production subsidies. We modeled and measured the potential impacts on global markets and the California industry that would result from reductions in trade barriers (such as import tariffs) and subsidies for the European Union’s processing tomato industry. A multi-equation simulation model showed that reducing trade barriers in Europe and elsewhere (including the United States) by 50% would raise the market price for California tomatoes by about 6%, improve net returns to California processing tomato producers by $34 million per year, and improve net returns to California tomato processors by $19 million per year. We also found that a 50% reduction in EU domestic support would improve the net returns of California producers and processors by about $8.5 million per year. Based on these results, we believe that negotiating reductions in subsidies, and especially in global trade barriers, would make economic sense for the California processing tomato industry.

California produces 95% of the processing tomatoes grown in the United States, and the processing tomato industry is an important component of California agriculture. Its total revenue was $670 million in 2004, ranking processing tomatoes 11th among all agricultural commodities produced in California (USDA 2005). Processed tomato products are also a major California export commodity.

About $250 million of processed tomato products were exported in 2004, accounting for approximately 12% of the crop; the industry ranked eighth among California agricultural commodities in value of exports (Bervejillo and Sumner 2005).

The United States and European Union each supply approximately one-third of the world’s processing tomatoes (fig. 1). There is little or no direct subsidy for processing tomatoes in the United States; however, processing tomato production is directly subsidized in the European Union with payments to growers. The EU subsidy regime for processing tomatoes is part of their overall system of subsidy, which also applies to other fruit and vegetable industries.

We investigated the consequences of EU processing tomato subsidies and global trade barriers for tomato producers and processors, especially in California. Through a simulation model, we show quantitatively how the removal of EU production subsidies would reduce EU production and exports, and raise prices in the global market. We also show that trade barriers (such as import tariffs) have even larger effects than subsidies.

Support for EU industry

The EU policy for processing tomatoes includes domestic support in the form of subsidies, import tariffs and an export subsidy (European Commission 2005). The subsidies are payments tied to the production of processing tomatoes. Import tariffs are a tax applied to processed tomato products entering the European Union, and export subsidies are paid to EU processors for selected tomato products that are exported.

From 1978 to 2000, EU domestic support included a complex array of direct transfers to processors (processor aid),...
Model parameterization

The proportional changes in prices and quantities are functions of various elasticity and share parameters. (Elasticities are used to represent the ratio between proportional change in one variable and proportional change in another.) The price elasticities of demand for the five processed tomato products were calculated from an overall price elasticity of demand for all processed tomato products, an elasticity of substitution between processed products and consumption shares (Armington 1969). The overall elasticity was set to −0.5, and was based on estimates from George and King (1971) and Huang (1985). The elasticity of product substitution was set to 5.0, reflecting the fact that tomato products are relatively close substitutes for each other.

The consumption shares were based on per-capita-consumption rates for processed tomato products (USDA 2005). The price elasticity of supply for processing tomatoes was assumed to be relatively inelastic and was set to 0.5, based on an estimate from Chern and Just (1978). The price elasticity of the manufacturing input supply was set to 1.0. The cost share for processing tomatoes was set to 45% for tomato paste and 20% for canned tomato products (based on estimates from a survey of industry experts). We allowed for some substitution between processing tomatoes and the manufacturing input, and this parameter was set to 0.1. (A value of 0 would indicate no input substitution; for perfect substitutes, the elasticity would be infinite.) The simulation model included raw tomatoes and processed tomato products, and we used a conversion rate of 6.1 tons of tomatoes per ton of tomato paste and 1.2 tons of tomatoes per ton of canned tomato products.

The effects of alternative values of several of these parameters, especially supply and demand elasticities, were also examined to test sensitivity in Rickard (2003). Our results are robust to changes in key parameters across a plausible range, and the main results for the most likely parameter values are reported here.

minimum prices for growers, and a quota that set a limit on the quantity eligible for the processor aid and minimum price. In 2000, processor aid was approximately $165 (€163) per ton of tomato paste; the minimum price for processing tomatoes was $81 (€80) per ton; and the minimum price was applied to approximately 7.7 million tons of processing tomatoes grown in Europe. (In January 2000, $1 was equivalent to €0.99; in January 2006, $1 was equivalent to €0.82.)

This subsidy program was changed beginning with the 2001 crop, and the changes have further stimulated EU production (Rickard 2003). Since February 2001, EU growers of processing tomatoes have received a per-ton subsidy from the European Union, as long as total EU production does not exceed the threshold limit of 9.1 million tons (8.25 million metric tons). In 2005, the subsidy rate was approximately $39 per ton and therefore, approximately 43% of per-unit revenue.

Since 2001, the EU tariff has been set at 14.4% for processed tomato products such as tomato paste and tomato sauce. The tariff rate has been reduced by one-fifth since 1995, in accordance with the Uruguay Round GATT deal, which is administered by the WTO. This tariff is refunded when the imported product is used in, or offset by, exports of processed tomato products. The European Union also allows reduced or zero tariffs for imports from selected developing countries. Export subsidies apply to certain canned tomato products, which make up a relatively small share of total processed tomato production in the European Union. For reference, the United States applies an import tariff of 12.5% to processed tomato products, and the average (nonweighted) tariff in other tomato-importing regions is approximately 20%.

The simulation model

We used an economic simulation model to assess the effects of lower EU domestic support and reduced border measures on the global processing tomato industry. There are three regions in our model: the European Union, the United States and the rest of the world. The model accommodates five processed products that are less-than-perfect substitutes for each other in consumption: (1) European Union–produced canned tomato products, (2) canned tomato products from other sources, (3) European Union–produced paste, (4) U.S. paste and (5) paste produced in other countries. In each of the three regions, two inputs (raw tomatoes and other inputs) are used in the production of these five processed tomato products. There is trade among the regions in processed tomato products but not in raw tomatoes.

The simulation model is used to perform experiments in policy reform; that is, to examine the effects that alternative policy scenarios would have on the processing tomato industry. We focus on reductions in domestic subsidies, export subsidies and tariffs. The European Union has the world’s only significant program of domestic subsidies for processed tomatoes, but many countries, including the United States, have import tariffs. It is implausible that import tariffs in the European Union would fall unilaterally; therefore, we considered multilateral reductions in import tariffs across all tomato-producing regions.

* Effects for the European Union and the rest of the world are available from the authors.
† California growers would earn more than 90% of the benefits. The gain of $34.6 million represents 6.4% of total producer revenue and a significantly larger percentage of net revenue.

combined with reductions in EU export subsidies and EU domestic support.

The simulation model used a set of equations to describe the supply and demand conditions for the processing tomato sector. Equilibrium adjustments can be simulated by specifying changes in the policy parameters, such as changes to EU domestic support or tariff rates. The model is used to simulate proportional changes in prices and quantities (and ultimately benefits or costs to producers and processors) for selected input and output markets in the processing tomato industry (see box, page 208).

Effects of policy reform

The simulation results describe how changes in EU export subsidies, global tariffs and EU domestic support would affect prices, quantities and net benefit measures, such as revenues and government expenditures. The focus is on the effects in the European Union and, especially, in California.

Export subsidies. The complete elimination of export subsidies would lower EU export tonnage by only 0.6%. The small impact of export subsidy reform is mostly attributed to the fact that the export subsidy rate is low and applies to only a small portion of total EU production. Because the impact of the EU export subsidy on the California industry is so small, the rest of our analysis focused on the effects of reductions in import tariffs and EU domestic support.

Tariffs. We found that a 50% cut in tariffs would increase the price and quantity produced in the European Union and the United States because both would export more to third markets, which begin with higher tariff rates (table 1). The price and quantity of processor-supplied inputs would also rise.

Domestic support. If EU production subsidies were cut by 50%, we found that per-unit grower returns in the European Union would fall, and market prices paid by EU processors for tomatoes would rise by 12.2% (table 1). The result is a decline in the quantity of tomatoes used and a decline in processor-supplied inputs as well. Cutting EU domestic support by this magnitude would have positive effects in the United States.

Import tariffs and domestic support. If the European Union cut production subsidies and all countries cut tariffs, there would be an increase in the price paid for tomatoes and a decrease in the price received by growers in the European Union (table 1). Reducing global tariffs and EU subsidies together would raise prices and quantities in the United States.

Benefits to U.S. producers and processors. The changes in prices and quantities (table 1) were then used to calculate changes in net processor revenues, net government expenditures or tariff revenues, and consumer benefits from tomato consumption in the United States (table 2). The annual net benefits to producers and processors from cutting the domestic subsidy in the European Union would be $5.5 million per year for U.S. growers and $3.0 million per year for U.S. processors.

The reduction in tariffs on a global basis would have a significantly larger effect on tomato processors and processors in the United States. The benefit to U.S. producers of tomatoes would be approximately $34 million per year, with about $32 million per year of that for growers in California. The increase in benefits to U.S. processors would be approximately $19 million per year, with almost all of

Negotiating reductions in subsidies, and especially in global trade barriers, makes economic sense for the California processing tomato industry.

in the European Union, and thereby increase the taxpayer cost of the EU domestic support regime. This would place additional pressure on EU budgets that could lead to reductions in subsidies as a response.

Producers and processors in the United States would gain about $8.5 million annually from a reduction in the EU subsidies, and the gain from tariff elimination would be even larger. This result of the simulations may seem surprising, because the initial tariff is only 14.4%, while the subsidy is 43%. The relative magnitude of the two impacts is driven by three factors.

First, the supply response of processing tomatoes in the European Union to lower per-acre returns (including policy benefits) is relatively inelastic in the intermediate time-frame because — for this analysis, and in the context of trade negotiations — we envision reductions in support for processing tomatoes as part of a larger, multicommodity package. Second, EU domestic support applies to the farm-produced product, and import tariffs apply to processed products. The farm product represents only 45% of the cost of tomato paste and 20% of the cost of canned tomato products, and barriers that apply at the border have bigger effects on trade than do subsidies for raw materials that are inputs to the tradable product. Third, the EU domestic support program drives a wedge between the price that growers receive and the price that processors pay for tomatoes. Reducing EU domestic support would reduce that wedge, and the burden of any reduction would be shared between the grower and processor.

Effects of trade negotiations

Trade negotiations have the potential to reduce trade barriers and farm subsidies on a global basis. The California processing tomato industry has long been concerned with subsidies and import barriers in the European Union. Our research shows that this interest is well placed, and although the effects of domestic subsidies are significant, to increase net returns the negotiations should emphasize trade barriers more than domestic subsidies in Europe. We also show that the California processing tomato industry would receive considerable benefits from global tariff reductions, even though that would mean giving up some of its own protection from imports.
