ABSTRACT

The total $K^+\cdot p$ cross section was measured at the three $K^+$-meson energies 175±25, 225±25, and 275±25 Mev, and the differential scattering cross section was measured at 225 Mev. The $K^+\cdot p$ nuclear force was shown to be repulsive, from the observed constructive interference with Coulomb scattering. The differential cross section was otherwise isotropic and could arise from either pure S-wave or pure P-wave scattering.

Subtracted dispersion relations were applied to these data and the rest of the available $K$-proton scattering data. The statistical errors in the data were found to be too large to determine the $K$-hyperon relative parity. On the assumption that the $K\Lambda$ and $K\Sigma$ relative parities are the same, then for scalar coupling, $g^2/4\pi$ would be less than 0.6; for pseudo-scalar coupling, it would be less than 10.
THE INTERACTION OF K\(^{+}\) MESONS WITH PROTONS

August 1959

I. INTRODUCTION

Information on the scattering of K\(^{+}\) mesons on protons is of the greatest importance, in that it may allow us to determine the nature of the K-meson-nucleon forces. Data at low energies have come mostly from the rare scattering of K\(^{+}\) mesons on hydrogen nuclei in emulsion. A compilation of the world total of 75 events was reported at the 1958 High Energy Physics Conference at CERN.\(^{1}\) The angular distributions in the three energy intervals 20 to 100 Mev, 100 to 200 Mev, and 200 to 300 Mev, considering the large uncertainties were not inconsistent with isotropy.

From a more recent compilation of data,\(^{2}\) total cross sections have been obtained as shown in Table I.

\(^{*}\)Work done under the auspices of the U. S. Atomic Energy Commission.

\(^{†}\) Present address: Brookhaven National Laboratory, Upton, New York

\(^{1}\) M. F. Kaplon, 1958 Annual International Conference on High Energy Physics at CERN.

\(^{2}\) D. H. Stork and D. J. Prowse (UCLA), private communication.
The purpose of this experiment was to measure the total $K^+$-meson-proton cross section at the higher energies—namely, $175\pm 25$, $225\pm 25$, and $275\pm 25$ Mev—as well as to determine the differential scattering cross section with small statistical errors at $225$ Mev. If the rise in total cross section should be due to a rising P-wave contribution, an asymmetry in the differential scattering cross section should be detected.

II. $K^+$-MESON SELECTION

A. The $K^+$-Meson Beam

The scattering-detection system required that the $K^+$ beam should be

(a) of angular divergence less than $2^\circ$ at the entrance to the liquid hydrogen target

(b) focused in an area of 1.25-in. diameter

(c) of energy spread no greater than $\pm 25$ Mev

(d) of an intensity greater than $25 K^+$ mesons per Bevatron pulse

These requirements were met for beam energies of $175\pm 25$, $225\pm 25$, and $275\pm 25$ Mev, with the arrangement illustrated in Fig. 1.

The $K^+$ mesons were produced in a tantalum target located in a Bevatron straight section, and entered the first of two 4-in.-aperture double-lens strong-focusing bending magnets. The first magnet momentum-analyzed the incoming particles, and focused the particles with the desired momentum at the lead slit. The beryllium was necessary to reduce the proton contamination. The second magnet refocused the selected particles at the scintillation counter.
B. $K^+$-Meson Identification

The portion of the beam that passes through the lead slit consists of $K^+$ and $\pi^+$ mesons and protons, but the particles focused at Counter D consist mainly of $K^+$ and $\pi^+$ mesons. The proton contamination at this point is negligible. The $K^+$ mesons are distinguished from the $\pi^+$ mesons by time of flight over the 8 feet between Counters 1 and D.

To attain a high time resolution for the identification system, the $K^+$ mesons were identified by requiring a coincidence of scintillation counters 1, 2, 3, D and anticoincidence with $\pi_A$; a velocity-threshold Čerenkov counter used to identify $\pi^+$ mesons. The $\pi^+$ contamination in the identified $K^+$ beam was measured to be less than 0.7%. A block diagram of the circuitry is shown in Fig. 2.

The R counter of Fig. 1 was used for range-energy measurements. By inserting copper between Counters D and R, we could determine the range distribution in copper, and thus the energy distribution of the $K^+$ mesons. Suitable corrections for $K^+$ decays between counters D and R were applied.

III. SCATTERING-DETECTION SYSTEM

Figure 3 shows the scattering angles of the $K^+$ meson and the proton in the laboratory system as a function of the angle in the center-of-mass of the $K^+$ meson, for elastic $K^+\text{-}p$ scattering. The kinematics are insensitive to incident $K^+$ energies in the range 175-275 Mev. It is seen that one and only one of the two particles enters a forward cone of half-angle $50^\circ$ (lab). Thus, to determine the angular distribution of the scattered $K^+$ mesons, it was sufficient to determine the angle of the forward-scattered particle and
then to identify the particle as being either a $K^+$ meson or a proton. The inelastic $K^+ - p$ scattering giving rise to $\pi$-meson production is assumed to be small.\(^3\)

After the energy of the $K^+$ beam was determined with the arrangement illustrated in Fig. 1, the $R$ counter was removed and the arrangement illustrated in Fig. 4 was placed behind the $D$ counter. The $T$ counter of Fig. 4 replaced the $R$ counter of Fig. 1 in the circuitry of Fig. 2.

The liquid hydrogen was contained in a thin-walled Mylar vessel 6 in. in length and 3 in. in diameter. A double bank of ring counters was used to determine the angle of the scattered particles. Each ring counter overlapped the adjacent one, to improve the angular definition. To define the scattering angle, it was necessary for at least one counter from each bank to count. With this arrangement, the scattering angle could be defined to within $\pm 5^\circ$ (lab).

The ring counter pulses, together with the $R$ pulse from counter $R$ of Fig. 4, the $C$ pulse from the water Čerenkov counter of Fig. 4, the $T$ pulse from the trigger counter of Fig. 4, and a timing pulse were displayed on an oscilloscope with the aid of the circuitry of Figs. 3 and 5, and the traces were photographed.

The water Čerenkov counter shown in Fig. 4 was used to identify the decay products originating from the large number of $K^+$ decays in the region behind the defining counter. Approximately 98% of the decay products originating from the six most common $K^+$ decay modes had velocities great enough to excite the Čerenkov counter. For the most part, the $C$ pulse from the water Čerenkov counter was used to blank the oscilloscope.

\(^3\) Helmy, Mulvey, Prowse, and Stork, "An Example of the Production of a $\pi^-$ Meson by a $K^+$ Meson."
The oscilloscope was allowed to record events in which the C pulse appeared only for that part of the experiment in which the ring counters were calibrated on the decay products.

The copper absorber and range counter, located behind the water Čerenkov counter in Fig. 4 were used to identify the scattered particle. The copper was just thick enough to stop the protons for all lab angles between 12° and 50°, while the \( K^+ \) mesons passed through the copper and registered in the range counter.

IV. THE TOTAL \( K^+ - p \) CROSS SECTION

The total \( K^+ - p \) cross sections at the three energies of 175±25, 275±25, and 275±25 Mev were obtained from the \( S_1 \) and \( S_2 \) scaler readings. The \( S_2 \) readings gave the number of \( K^+ \) mesons passing through the defining counter, whereas the \( S_1 \) reading gave the number of \( K^+ \) mesons that passed through the defining counter but did not reach the \( T \) counter. The \( S_1 \) and \( S_2 \) readings were accumulated for "target full" and "target empty," for each of the three energies. Table II lists these numbers as well as the ratios of \( \frac{S_1}{S_2} \), which are the fractions of \( K^+ \) mesons removed from the \( K^+ \) beam.
Table II. Summary of scaler readings.

From the target-empty data in Table II, one sees that the background from decays, scattering in the walls of the target, and scattering in the defining counter is approximately 10 to 15 times as large as the effect under investigation. The total cross section was obtained from the difference of the two relatively large quantities $S/S_2|f$ and $S/S_2|e$ by means of Eq. (1), which takes into account as well as possible the difference in decay rates for "target full" and "target empty" conditions. The background from wall scattering, etc. was small in comparison with the decay background, and was presumed to be the same for both "target full" and "target empty" conditions. In addition, the "target empty" condition actually included scatterings from the hydrogen gas still in the "empty" target. The gas density at that temperature is approximately 2% of the liquid density.
Assuming all decays and scattering events to take place on the beam axis, and neglecting multiple scatters, we have

\[ \frac{N(x_1)}{N(x_0)} = \exp \left\{ - \int_{x_0}^{x_1} \left[ \lambda_s(x) + \lambda_D(x) \right] dx \right\}, \]  

where \( N(x_1) \) is the number of \( K^+ \) mesons in the beam at point \( x_1 \);

\( N(x_0) \) is the number of \( K^+ \) mesons in the beam at point \( x_0 \);

\( \lambda_s(x) = n(x)\sigma(x) \); \( n(x) \) = target nuclei density, and \( \sigma(x) \) is the cross section for scattering into angles great enough to miss the T counter;

\( \lambda_D(x) \) is the reciprocal decay length for decays in which the charged decay product misses the T counter;

\( x_1 \) is taken at the T counter, so that \( N(x_1) = 1 - \bar{S}, \bar{S} = \bar{S} \)-scaler reading.

\( x_0 \) is taken immediately before the D counter, so that \( N(x_0) = S_2, S_2 = S_2 \)-scaler reading.

The integrals \( \int_{x_0}^{x_1} \left[ \lambda_s(x) + \lambda_D(x) \right] dx \) were performed for "target full" and "target empty;" \( \bar{S}/S_2 \)-scaler data were substituted into the left side of Eq. (1), and then Eq. (1) was solved for the \( K^+ \)-p cross section for scattering into angles \( > 12^\circ \). The results of the calculations are given in Table III. The experimental error in the \( K^+ \)-meson half life led to a calculated error of \( < 1\% \) in the total cross section, and was neglected.
V. THE K⁺-p DIFFERENTIAL CROSS SECTION

A. Calculation of the Differential Cross Section

Owing to the added complexity of the problem and the relatively small decay-background counting rate in the ring counters, the incorporation of corrections into the data for the determination of the differential cross section was different than for determination of the total cross section. Instead of being found from one formula incorporating all correction factors, the differential cross section was determined in the following way, and the corrections were applied later.

Assuming all events to take place on the axis of the target, let $P_g(\theta, x) \, d\theta \, dx$ be the probability that a scattering event occurs in the interval $dx$ at $x$, and scatters into angular interval $d\theta$ at $\theta$. Let $P_c(\theta, x) \, d\theta \, dx$ be the probability that the ring counter combination, $c$, will receive scatterings (into $d\theta$ at $\theta$) that occur in $dx$ at $x$. Let $\epsilon$ be the counting efficiency of counter combination $c$. Let $S_c$ be the experimental number of events detected by the counter combination $c$ as ascertained from the film data. Then $\frac{S_c}{S_2}$ full is the fraction of the incident $K^+$ mesons that scattered into counter combination $c$. We may then write

Table III. Corrected total $K^+$-p cross sections from scaler date.

</tbody>
</table>
where $\theta_1$, $\theta_2$ are the limiting angles at which counter combination "c" can detect a scattering event, and $x_1(\theta)$ are the limiting positions in the target at which c can detect (in de at $\theta$) a scattering event that occurs in dx at x. Now $P_s(\theta, x)$ can be approximated by

$$P_s(\theta, x) = n \frac{d\sigma}{d\theta}|_L,$$ 

where $n$ is the number of protons per unit length of axis (assumed to be constant); and $\frac{d\sigma}{d\theta}|_L$ is the differential scattering cross section in the laboratory system. The effect of decrease in $K^+$-meson flux along the axis of the target, which renders Eq. (3) only an approximation, is treated as a correction to be applied later. We then have, from Eq. (2),

$$\frac{S_c}{S_2}_{\text{full}} - \frac{S_c}{S_2}_{\text{empty}} = \xi \left( \frac{d\sigma}{d\theta} \right) \int_{\theta_1}^{\theta_2} \int_{x_1(\theta)}^{x_2(\theta)} P_c(\theta, x) dx \, d\theta,$$ 

and

$$P_c(\theta) = \int_{x_1(\theta)}^{x_2(\theta)} P_c(\theta, x) \, dx.$$ 

For each counter combination considered, it was found that $P_c(\theta)$ was
fairly symmetric about \((e_1 + e_2)/2\). Thus, since \(d\sigma/d\theta|_L\) is independent of \(x\) and is assumed to be a slowly varying function of \(\theta\), we have, from Eq. (5),

\[
\frac{d\sigma}{d\theta} \bigg|_L \approx \frac{d\sigma}{d\theta} \bigg|_L \left(\frac{\theta_1 + \theta_2}{2}\right),
\]

where the right side of this last expression is to be interpreted as \(d\sigma/d\theta|_L\) considered as a function of \(\theta_{\text{lab}}\) and evaluated at \((\theta_1 + \theta_2)/2\).

The \(P_c(\theta)\) for each counter combination were obtained by the Monte Carlo method, using an IBM 701 computer. One thousand scattering events were simulated by the computer at each \(\theta\) in 1-degree intervals at random positions and at random azimuthal angles inside the hydrogen target. The efficiency factor \(\xi\) for each counter combination was determined by comparing the observed counts from K-meson decays with theoretical values. The counts from decays were obtained by turning off the Cerenkov blanking pulse to the oscilloscope. The theoretical values were calculated on the basis of isotropic decay in the center-of-mass system for each decay mode.

More than 100 counter combinations were used to obtain the differential cross section. To improve the statistics and make the approximation of Eq. (6) more accurate, counter combinations were grouped together so that their combined counts indicated scatters into \(\pm 10^\circ\) about \(\theta\) (c.m.).

B. Corrections

Correction factors were applied, taking into account: (a) decays of the scattered mesons, (b) scattered \(K^+\) mesons that interact in the Cu absorber and (c) decrease in K flux along the axis of the target. These
corrections were a function of angle, and amounted to about 10%. The corrected results of the calculations based on Eqs. (4) and (6) and the transformation to center-of-mass coordinates are given in Fig. 6, where 
\[ \frac{d\sigma}{d\Omega} = \left( \frac{1}{2\pi} \sin \theta \right) \frac{d\sigma}{d\theta} \bigg|_{\text{cm}}. \]

From the phase-shift analysis described in the next section, using the \( S_{1/2} \) \( K^+ \)-p scattering-state phase shift obtained from the data of Fig. 6, the total \( K^+ \)-p scattering cross section was calculated as \( \sigma_T = 15.3 \), in good agreement with the value 15.2±1.3 mb obtained from the scaler data.

VI. PHASE-SHIFT ANALYSIS

The angular distribution of the scattering of \( K^+ \) mesons from protons has been analyzed in terms of an expansion in partial waves. We assumed that since \( \lambda = 0.6 \times 10^{-13} \) cm, the compound \( K^+ \)-meson-nucleon states responsible for the scattering were \( s_{1/2} \), \( p_{1/2} \), \( p_{3/2} \). From the assumption of charge independence for the nuclear interaction between the \( K \) meson and nucleon, it follows the \( K^+ \) mesons are scattered from protons in a pure \( T = 1 \) isotopic spin state. The number of phase shifts necessary to describe the differential cross section was thus reduced to three, namely, \( \delta_0 \), and \( \delta_1 \), and \( \delta_3 \) for scattering in the \( s_{1/2} \), \( p_{1/2} \), and \( p_{3/2} \) states, respectively. It is possible to determine experimentally the absolute signs of the phase shifts from the interference of the nuclear scattering with the Coulomb scattering.
The differential cross section in the center-of-mass system for scattering without and with spin flip and including the Coulomb effect is

\[
\frac{d\sigma}{d\Omega} = \frac{\lambda^2}{4} \frac{|-ia|}{\sin^2(\theta/2)} \exp \left( -i\frac{a}{2} \log \sin^2 \frac{\theta}{2} \right) \left( P + Q \cos \theta \right)^2, \tag{7}
\]

\[
\frac{d\sigma}{dT} = \frac{\lambda^2}{4} |R|^2 \sin^2 \theta, \tag{8}
\]

where \( \lambda \) is the de Broglie wavelength of the \( K^+ \) meson in the center-of-mass system,

and

\[
a = \frac{\mu e^2 \lambda^2}{\hbar^2 (1 - \beta^2)^{1/2}}:
\]

\( \mu, e, \) and \( \hbar \) are the reduced mass of the \( K^+ \)-meson-proton system, the \( K^+ \)-meson charge, and Planck's constant, respectively;

\( \beta \) is the velocity of the \( K^+ \) meson relative to the proton;

\( P = e^{2i\delta_0} - 1, \)

\( C = \frac{1+ia}{1-ia} \sin \delta_1 e^{i\delta_1} - 2 \sin \delta_3 e^{i\delta_3} \)

\( R = \sin \delta_3 e^{i\delta_3} - \sin \delta_1 e^{i\delta_1}. \)

\[4 \text{ L. Van Hove, Phys. Rev. 91, 947 (1953).}\]
Some simplification is possible. For a $K^+$-meson energy of 225 Mev, $a = 0.014$. Thus, $a$ can be neglected in $C$ without contributing more than 3% uncertainty in the scattering amplitude. The expression $\exp(-ia \log \sin^2 \theta / 2)$ can be set equal to unity for $\theta > 20^\circ$, for $a \log \sin^2(\theta/2) < 0.02$.

The combination of the differential cross sections for scattering without and with spin flip, in units of $\chi^2$, is

$$\frac{1}{\chi^2} \frac{d\sigma(\mu)}{d\Omega} = \left\{ \frac{-ia}{1-\mu} \sin\delta_0 \ e^{i\delta_0} + \left( \sin\delta_1 \ e^{i\delta_1} + 2 \ \delta_3 \ e^{i\delta_3} \right) \mu \right\}^2 + \left( \sin\delta_3 \ e^{i\delta_3} - \sin\delta_1 \ e^{i\delta_1} \right)^2 (1 - \mu^2),$$

(9)

where $\mu = \cos \theta$.

A good fit of $\frac{1}{\chi^2} \frac{d\sigma(\mu)}{d\Omega}$ to the experimentally determined differential cross sections corresponds to a minimum in

$$\chi^2 = \sum_i \left( \frac{y(\mu_i)}{\sigma(\mu_i)} - \frac{1}{\chi^2} \frac{d\sigma(\mu_i)}{d\Omega} \right)^2,$$

(10)

where $y(\mu_i)$ and $\sigma(\mu_i)$ are the experimental cross sections and their statistical errors respectively. The IBM 650 computer was programmed to calculate $\chi^2$ from Eqs. (9) and (10) for a set of arbitrary values of the three phase shifts, $\delta_0$, $\delta_1$, $\delta_3$. One of the phase shifts was then increased by 0.01 radian, and the $\chi^2$ recalculated. If the new $\chi^2$ was smaller than the previous one, the phase shift was changed again in the same direction. If $\chi^2$ was larger, the phase shift was then decreased.
The process was repeated until $\chi^2$ reached a minimum, and then another phase shift was varied. When $\chi^2$ could not be made smaller by changing any of the three phase shifts, the computer gave the result. By starting with various sets of initial phase shifts, three solutions were found that gave a $\chi^2$ small enough to be considered significant. These are given in Table IV. The $\chi^2$ for each solution, as well as the confidence level, is listed. The fit with $\delta_0 > 0$ and $\delta_1 = \delta_3 = 0$ gave a confidence of less than 1%.

Table IV. Phase-shift combinations that give good agreement with experimental data.

The $\delta_0^-$ and $\delta_1^-$ solutions correspond to interactions in virtually pure $s_{1/2}$ and $p_{1/2}$ states, respectively, with phase shifts of approximately $-33^\circ$. Both solutions also agree with the forward peaking in the cross section, indicating a repulsive nuclear potential. For the $\delta_1^+$ solution, the rise in the determined measured cross section at $25^\circ$ and $35^\circ$ does not agree with the predicted drop. The ambiguity between $\delta_0^-$ and $\delta_1^-$ is considered in greater detail in the following section.

VII. DISCUSSION

A. Total Cross Section

Knowledge of the $K^+$-meson-proton interaction has been extended to intermediate kinetic energies. Our results in Table III confirm the
increase in $K^+$-meson-proton cross section as a function of energy found from the scattering of $K^+$ mesons on free protons in nuclear emulsion. Our averaged cross section over the energy interval from 200 to 300 Mev is $15.6\pm1.0$ mb, which agrees within the statistical errors with $18.0\pm3.5$ mb obtained from emulsion events (for comparison, the cross section below 100 Mev is $13.5\pm2.5$ mb). The threshold for $\pi$-meson production by $K^+$ mesons on protons is 225 Mev. Our total cross sections include the contribution from $\pi$-meson production, but no estimate of the magnitude could be made.

Recent data from 600 Mev to 2 Bev indicate that the total cross section rises to $19.6\pm1.2$ mb at 700 Mev and then gradually drops to $13.0\pm1.0$ mb at 2 Bev.

The over-all behaviour of the $K^+$-meson-proton cross section as a function of energy is not understood at present.

B. The Nature of the $K^+$-Meson Force

Of the three phase-shift combinations that were found to fit the angular distribution of the scattered $K^+$ mesons, only two (namely, $\delta_0$ and $\delta_1$) gave good agreement with the small-angle scattering. Although both solutions are about equally probable, it is important to note that both correspond to a repulsive $K^+$-meson-proton force. This evidence in favor of the repulsive nuclear force is indeed the most direct and conclusive. Supporting evidence has come in the past from the optical-model analyses of inelastic scattering of $K^+$ mesons from emulsion nuclei.

---

C. The Differential Scattering Cross Section

The $\delta_0^-$, $\delta_1^-$ ambiguity in the phase shifts to the experimental data cannot be easily resolved. For the $\delta_1^-$ solution, one would expect the recoil proton to be polarized. However, since the polarization arises from the interference with the Coulomb scattering, the predicted value has a maximum of $P(\theta = 0.07$ for $\theta = 70^\circ (\text{lab})$. It may be easier to resolve the ambiguity by measuring the differential cross section of $K^+$ mesons scattering from protons at lower energies. If the differential cross section is isotropic for all energies, and if one assumes that $K^+$ mesons scatter in the $S$ wave at very low energies, then the $\delta_0^-$-phase-shift combination must be the true solution. This follows from the fact that to change from pure $S$-wave scattering to pure $P_{1/2}$-wave scattering, the cross section must be anisotropic in the energy interval in which both $S$ and $P$ waves contribute to the scattering cross section.

D. Use of $K^+-p$ Dispersion Relations

The form of the $K-p$ dispersion relations is

\[
D_+ (\omega) = \frac{1}{4\pi^2} \int_1^{\infty} \frac{k'_+ (\omega)}{\omega^+ \omega^+ \omega} \, d\omega' + \frac{1}{4\pi^2} \int_1^{\infty} \frac{k'_- (\omega')}{\omega^- \omega^- \omega} \, d\omega'
\]

\[
+ \frac{1}{4\pi^2} \int_{\omega_{\Lambda \tau}}^{1} \frac{4\pi \Lambda_- (\omega')}{\omega^+ \omega^-} \, d\omega' + \frac{P_{\Lambda \tau} X(\Lambda)}{\omega^+ \omega^-} + \frac{P_{\Sigma} X(\Sigma)}{\omega^+ \omega^-} + C,
\]  \hspace{1cm} (11)

where $D_{\pm}$ is the real part of the $K^+$-proton forward-scattering amplitude, in units of $K$-meson Compton wavelength ($\lambda_K$); $k'$ is the laboratory-system momentum, in units of $m_k c$; $\omega'$ and $\omega$ are laboratory-system energies of the $K$ meson, in units of $m_k c^2$; $\sigma_+ (\omega')$ and $\sigma_- (\omega')$ are the $K^+ - p$ and $K^- - p$ total cross sections, respectively, in units of $K$-meson Compton wavelength, squared; $A_-$ is the imaginary part of the $K^- - p$ forward-scattering amplitude, in units of $K$-meson Compton wavelength; $C$ is a constant.

The purpose of this section is to investigate the possibility of determining $p_\Lambda (\rho_\Sigma)$ and $\chi (\Lambda) \langle \chi (\Sigma) \rangle$, which are the sign and magnitude of the residues at $\omega = m_\Lambda (m_\Sigma)$, respectively, where

$$\chi_{\Lambda, \Sigma} = \frac{g_{\Lambda, \Sigma}^2}{4 \pi} \left[ \frac{(m_\Lambda, \Sigma \pm m_p)^2 + m_k^2}{4 m_p m_\Lambda} \right], \text{ for } p_{\Lambda, \Sigma} = \pm 1. \quad (12)$$

The quantities $p_\Lambda$ and $p_\Sigma$ are either $+1$ or $-1$, depending upon the parity of the $K$-hyperon-nucleon system. We have

$$\omega_a = \frac{m_a^2 - m_p^2 - m_k^2}{2 m_p}, \quad (13)$$

where $m_a$ is the rest energy of the $\alpha$ system ($\omega_\Lambda = 0.129 m_k$, $\omega_\Sigma = 0.313 m_k$, and $\omega_{\Lambda \pi} = 0.498 m_k$).

Of the various subtracted dispersion relations proposed, none is adequate at present for the experimental data now available. The following form, however, has several decisive advantages.
\[
\omega_0\ D^+(\omega) - \frac{1}{2} \ (\omega_0 + \omega) \ D^+ (\omega_0) - \frac{1}{2} \ (\omega_0 - \omega) \ D^- (\omega_0)
\]

\[
= \frac{1}{4\pi^2} \int_{1}^{\infty} \left[ \frac{\omega_0 \ k' \ \sigma^+ (\omega')}{\omega' - \omega} - \frac{(\omega_0 + \omega) k' \sigma^+_+ (\omega')}{{2(\omega' - \omega_0)}} - \frac{(\omega_0 - \omega) k' \sigma^+_+ (\omega')}{{2(\omega' + \omega_0)}} \right] d\omega'
\]

\[
+ \frac{1}{4\pi^2} \int_{1}^{\infty} \left[ \frac{\omega_0 \ k' \ \sigma^- (\omega')}{{\omega' + \omega}} - \frac{(\omega_0 + \omega) k' \sigma^-^- (\omega')}{{2(\omega' + \omega_0)}} - \frac{(\omega_0 - \omega) k' \sigma^-^- (\omega')}{{2(\omega' - \omega_0)}} \right] d\omega'
\]

\[
+ \frac{1}{4\pi^2} \int_{1}^{1} \left[ \frac{\omega_0 \ 4\pi \ A^+ (\omega')}{{\omega' + \omega}} - \frac{(\omega_0 + \omega) 4\pi \ A^+ (\omega')}{{2(\omega' + \omega_0)}} - \frac{(\omega_0 - \omega) 4\pi \ A^+ (\omega')}{{2(\omega' - \omega_0)}} \right] d\omega'
\]

\[
+ p_{\Lambda} \ X(\Lambda) \left[ \frac{\omega_0}{{\omega_\Lambda + \omega}} - \frac{\omega_0 + \omega}{{2(\omega_\Lambda + \omega)}} - \frac{\omega_0 - \omega}{{2(\omega_\Lambda - \omega)}} \right]
\]

\[
+ p_{\Sigma} \ X(\Sigma) \left[ \frac{\omega_0}{{\omega_\Sigma + \omega}} - \frac{\omega_0 + \omega}{{2(\omega_\Sigma + \omega)}} - \frac{\omega_0 - \omega}{{2(\omega_\Sigma - \omega)}} \right].
\]

(14)
If \( \omega_0 \) is set equal to \( m_k \) in (14), Igi's form is obtained. The above form, however, has the advantages of Igi's in that the cross-section integrals converge rapidly and depend more on the \( K^+ - p \) cross sections than on those of \( K^- - p \). These cross-section integrals converge, even if the cross sections go to a constant as \( \omega \) goes to infinity. An additional advantage of form (14) is that the real parts of the forward-scattering amplitudes are used at energies for which they are known from experiment, rather than at the rest energy. Furthermore, the contribution from the unphysical region is decreased by displacing a singularity from its position at \( m_k \) to \( \omega_0 \).

The latest experimental \( K-p \) total cross sections were used for \( k \sigma \pm(\omega) \); a smooth curve was fitted to the experimental points, and an extrapolation of \( 4\pi A_\pm \) was made into the unphysical region. More precise estimates on the extrapolation into the unphysical region have been carried out by Dalitz and Tuan. Their values do not materially affect the conclusions from the dispersion relations. Since the dispersion relation in Eq. (14) does not weight the high-energy region, it was possible to make cutoffs at \( \omega = \pm 4 \). The statistical errors were estimated to be 10% for the integral under the smooth curve fitted to \( k \sigma_+(\omega) \), and 15% for \( k \sigma_-(\omega) \). Figure 7 shows a typical integrand for the integral of Eq. (14). The experimental points are shown, to indicate the effect of the experimental uncertainties.

The quantity $D_{\pm} (\omega)$ was obtained from

$$
D_{\pm} (\omega) = \pm \frac{\omega}{m_p} \sqrt{\frac{d\sigma_{\pm}^{el}}{d\Omega} (\omega)|_{\theta=0} - \frac{k_b^2}{16\pi^2} \left( \sigma_{\pm} (\omega) \right)^2},
$$

(15)

where $\omega$ and $k_b$ are respectively, the total energy and K-meson momentum in the center-of-mass frame. The sign of $D_{\pm} (\omega)$ is plus or minus, depending upon whether the $K^+$-proton force is attractive or repulsive, respectively.

From the experiment being described, it has been seen that the $K^+$-p interaction is repulsive, thus making $D_+ (\omega)$ negative. The nature of the $K^-$-p force is still unknown, and this causes $D_- (\omega)$ to be uncertain in sign.

From the $\delta^0$-phase-shift combination, $\frac{d\sigma_{+}^{el}}{d\Omega} (1.46)|_{\theta=0}$ is 1.21±0.16 mb/sterad. If one assumes, as has been done here, that for lower $K^+$-meson energies $\frac{d\sigma_{+}^{el}}{d\Omega} (\omega)$ is isotropic, then $\frac{d\sigma_{+}^{el}}{d\Omega} (\omega)|_{\theta=0}$ simply becomes $\sigma_{+}^{el} (\omega)/4\pi$. Furthermore, $\sigma_{+}^{el} (\omega) = \sigma_{+}(\omega)$ for $\omega < 1.46$.

Thus, sufficient information is available for the determination of $D_+ (\omega)$ for $\omega = 1.0$, 1.17, 1.285, and 1.46.

The value of $D_- (\omega)$ is obtained from Eq. (15) in a similar way, but for $\omega = 1.17$ and $\omega = 1.285$. From bubble-chamber data, we have

$$
\frac{d\sigma_{-}^{el}}{d\Omega} (1.17)|_{\theta=0} = 5.2\pm1 \text{ mb/sterad}, \text{ while } \frac{d\sigma_{-}^{el}}{d\Omega} (1.285)|_{\theta=0} \text{ is still not available.}
$$

The total $K^-$-p cross sections for the two energies are $\sigma_- (1.17) = 91\pm9 \text{ mb and } \sigma_- (1.285) = 86\pm7 \text{ mb}$. The value obtained for

---

13 R. D. Tripp, (Lawrence Radiation Laboratory), private communication.
D_ - (1.17) is of the order of 0.5 K-meson Compton wavelength. For the higher energy, D_ - (1.285) is on the order of zero if \( \frac{d\sigma_{el}}{d\Omega} (1.285) \big|_{\theta=0} \) is assumed to be not much larger than 8.2 mb/sterad. This is not an unreasonable assumption, since \( \sigma_{el} (1.285) = 44 \pm 8 \) mb. Thus D_ - is small enough so that only a truly surprising change in the experimental data could change D_ - enough to alter its effect in Eq. (14). The results of the calculations of \( D \pm (\omega) \) are listed in Table V. The calculations have also been carried out using the results of Dalitz for D_ - with no essential difference in the results.

Since it is clearly not possible to solve for \( p_\Lambda g_\Lambda^2/4\pi \) and \( p_\Sigma g_\Sigma^2/4\pi \) separately, we have assumed \( p_\Lambda = p_\Sigma = p \) and \( g_\Lambda^2 = g_\Sigma^2 = g^2 \). By substituting the above experimental data into Eqs. (12) and (14), we can solve for \( p g^2/4\pi \) for four different sets of values of \( \omega \) and \( \omega_0 \). The results are listed in Table VI.

We see that for an attractive $K^-p$ potential $D_-$ is positive and a pseudoscalar coupling is favored; for a repulsive $K^-p$ potential, $D_-$ is negative and a scalar coupling is favored. If $D_-$ is assumed to be negligible, the results from the first two rows favor a pseudoscalar coupling; those from the second two rows, a scalar coupling. The value of $g^2/4\pi$ varies about zero, but the variation is well within the statistical error. It is thus impossible to determine whether the coupling is scalar or pseudoscalar, but if it were scalar, $g^2/4\pi$ would be less than about 0.6; if pseudoscalar, less than about 10. These results indicate that even with the most recently available data it is difficult, from subtracted dispersion relations, to arrive at unambiguous conclusions as to the nature of the $K$-meson - hyperon coupling.
VIII. ACKNOWLEDGMENTS

The encouragement and help at all times of Dr. Robert Birge, Dr. Marian Whitehead, and Dr. Robert Lanou is greatly appreciated. Mr. Michael Austin, Mr. Victor Cook, Mr. Robert Matsen, Mr. Gerald Schnurmacher, and Mr. Thomas Tonisson are thanked for their assistance during the actual running of the experiment. We are grateful for the help of Mr. Robert Fry, Mrs. Edith Goodwin, Mrs. Beverly Jerome, Mr. Layton Lynch, Mr. David Marsh, Mrs. Marilynn McLaren, Mr. Joseph Waldman, and Mr. Robert Young in scanning the enormous length of film. Mr. Jonathan Young, for his skillful programming and running of the IBM 701 computer, and Dr. Edward J. Lofgren and the operating crew of the Bevatron, for their efficient operation of the machine, deserve grateful recognition. We also wish to thank Dr. Robert Karplus for valuable discussions on the application of dispersion relations.
FIGURE CAPTIONS

Fig. 1. Beam arrangement. $K^+$ mesons were produced in a tantalum target and, after the elimination of proton contamination by means of a beryllium absorber, were focused on Counter D.

Fig. 2. Block diagram of $K^+$-meson identification circuitry. Coincidences and anticoincidences were taken between counters 1, 2, 3, D, and $\pi_A$, and scaled. The $S_2$ scaler then indicated the number of $K^+$ mesons that entered the target; the $S_1$ scaler indicated the number of $K^+$ mesons that passed through the target; the $S$ scaler indicated the number of $K^+$ mesons that disappeared from the beam between Counters D and R. The $S$ anticoincidence-circuit pulse triggered an oscilloscope, upon which were displayed the ring-counter pulses.

Fig. 3. The laboratory system scattering angle of protons and $K^+$ mesons, as a function of the center-of-mass system scattering angle of the $K^+$ meson, for a $K^+\cdot p$ elastic scattering event.

Fig. 4. Arrangement of liquid hydrogen target and scattering-detection scintillation counters. The line of flight of the scattered particle is determined by the double bank of ring counters, and the particle is identified by its range in copper.
Fig. 5. Block diagram of scattering-detection circuitry. In the multichannel coincidence circuit, the scattering-detection scintillation-counter pulses are put into coincidence with an $S_2$-coincidence-circuit pulse and then displayed on an oscilloscope.

Fig. 6. The $K^+\cdot p$ differential scattering cross section at $225 \pm 25$ Mev, in units of the square of the center-of-mass system de Broglie wavelength of the $K^+$ meson. The curves labeled $\delta_0^-, \delta_1^-$, and $\delta_1^+$ are least-square fits for, respectively, $S_{1/2}$ - state scattering with repulsive nuclear potential, $P_{1/2}$ - state scattering with repulsive nuclear potential, and $P_{1/2}$ - state scattering with attractive nuclear potential.

Fig. 7. The combined integrands of Eq. (14) for $\omega = 1.46$, $\omega_0 = 1.17$, and a smooth extrapolation of $A_-$ into the unphysical region. The singularities of the integrand are indicated by vertical lines.
