#### Abstract

Trifluoromethanesulfonic acid and other electrophiles promote formation of the adamantanone core from the readily accessible 1,5-dimethyl-3,7-dimethylene-bicyclo[3.3.1]nonan-9-one 2. Because adamantyl cation 3 can be trapped by a range of nucleophiles, including aromatic and heteroaromatic rings, alcohol, nitriles, and halides, access to a wide variety of functionality at the newly formed tertiary position is provided.

The Friedel-Crafts alkylation of benzenoid aromatic rings with the adamantane core has been reported occasionally, but harsh conditions, including high temperature, long reaction times, and high pressure mercury lamps, were often employed. ${ }^{7}$ In many cases, a multistep procedure is involved in which a 1 haloadamantane is first formed and then used to generate a carbocation at the tertiary position, which is subsequently trapped by a nucleophile. Although there is one example of the cyclization of the simple unsubstituted 3,7-dimethylenebicyclo[3.3.1]nonane in anisole as solvent giving the aryl adamantane, ${ }^{8}$ to our knowledge, no systematic study of the Friedel-Crafts alkylation of adamantyl cations generated by this type of cyclization has been carried out. This limited reaction scope therefore prompted us to investigate a more efficient way of rapidly constructing substituted adamantanones.

Synthesis of Adamantanones from 2. We now present a new and efficient method for the construction of adamantan-2ones substituted at the 7-position with aryl, heteroaryl, alkoxy, amido, and alkynyl groups, starting from the 1,5 -dimethyl-3,7dimethylenebicyclo[3.3.1] nonan-9-one core 2 . We envisioned forming the adamantyl cation with acid, followed by trapping with a nucleophile to obtain the tetrasubstituted adamantanone core. Consequently, we screened various acidic conditions for the formation of the desired product, 1,3,5-trimethyl-7-phenyladamantan-2-one 4a, from 2 (Table 1).

Without the presence of an added nucleophile, the cation can be quenched by the benzene solvent. Thus, treatment of the diene 2 with trimethylsilyl triflate in benzene afforded the 7 -phenyl-substituted adamantanone 4 a in $65 \%$ yield. Other protic and Lewis acids produced the same product $\mathbf{4 a}$ in moderate to good yields, with trifluoromethanesulfonic acid, triflic acid, being the best of those tested, giving the desired product in

$90 \%$ yield. Some Lewis acid catalysts, e.g., cupric triflate, did not provide any product but only returned starting material.

Substrate Scope. Next, we investigated the substrate scope of our reaction using the same mild conditions and short reaction times (Table 2). Various aromatic rings with electron-

${ }^{a}$ Reaction conditions: $\mathbf{2}(1.05 \mathrm{mmol})$, TfOH ( 1.2 equiv), nucleophile ( 5.0 equiv), $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \mathrm{~mL}), \mathrm{Ar}, 3 \mathrm{~h}$, unless otherwise specified. ${ }^{b}$ Reactions are performed with nucleophile as solvent.
donating groups $\mathbf{5 a - e}$ reacted as good nucleophiles to produce the substituted adamantanones $4 \mathbf{a}-\mathbf{e}$ in moderate yields. Thus, toluene $\mathbf{5 b}$ gave a $76 \%$ combined yield of a $3: 1$ mixture of the 4 -methyl and 2 -methyl products $\mathbf{4 b}$ and $4 \mathbf{b}^{\prime} . p$-Xylene $5 \mathbf{c}$ gave the expected product 4 c in $47 \%$ isolated yield; similarly, $m$ dimethoxybenzene $5 \mathbf{d}$ afforded the expected product 4 d in $47 \%$ yield. The more hindered $1,3,5$-trimethoxybenzene 5 e gave the expected product $4 \mathbf{e}$ in only $36 \%$ yield, perhaps due to the steric hindrance of the only available aromatic position. Again, there have been scattered reports of the trapping of adamantyl cations with benzenoid nucleophiles, but no systematic study has been reported. ${ }^{9}$ As far as we can tell, no heterocycles have ever been used to trap an adamantyl cation under these conditions. Therefore, we studied the use of several fivemembered heterocyclics in this regard (Table 3). Furan and $N$ methylindole gave very poor results, with a multitude of

${ }^{a}$ Reaction conditions: $2(1.05 \mathrm{mmol})$, TfOH ( 1.2 equiv), nucleophile (5.0 equiv), $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \mathrm{~mL})$, unless otherwise specified. ${ }^{b}$ Reactions performed with nucleophile as solvent. ${ }^{c}$ Conc. $\mathrm{H}_{2} \mathrm{SO}_{4}$ as solvent.
unidentified products being formed. However, the reaction of 2 in the presence of triflic acid with $N$-methylpyrrole 5 f gave a mixture of the 2 - and 3 -substituted pyrrole products, $\mathbf{4 f}$ and $\mathbf{4 f}^{\prime}$, in yields of 33 and $17 \%$, respectively. The assignment of the structures was based on the pattern of the absorptions in the proton NMR spectrum and matched literature data. ${ }^{10}$ In this case, the ratio of the trapping at C 2 vs $\mathrm{C} 3(1.9: 1)$ is somewhat surprising given that the reported ratio of trapping of a tertbutyl cation with $N$-methylpyrrole is 1:1.4 (C2/C3). ${ }^{11}$ Likewise, reaction of 2 with thiophene 5 g in the presence of triflic acid afforded the 2 - and 3 -substituted products, 4 g and $4 \mathbf{g}^{\prime}$, in a 1.2:1 ratio in yields of 26 and $21 \%$, respectively. The assignment was made by comparing the coupling constants for the three aromatic protons and by analogy to literature data. ${ }^{12}$

In addition to trapping the adamantyl cation, generated from 2 by protonation with triflic acid, with aromatic nucleophiles, we also investigated trapping with other simple nucleophiles. Again, there are reports of such nucleophilic trapping in the literature, ${ }^{8,13}$ but no systematic study has been carried out. Thus, we treated the diene 2 with triflic acid in the presence of various nucleophiles, with the results shown in Table 3. Methanol and acetic acid as nucleophilic solvents gave good yields of the expected trapping of the oxygen atom to produce $4 h$ and $4 \mathbf{i}$ in 52 and $88 \%$ yields, respectively. The tertiary alcohol 4 j could also be prepared by treating 2 with conc. sulfuric acid in $74 \%$ yield. Propargyl alcohol also trapped on oxygen to give the propargyl ether $4 \mathbf{k}$ in $35 \%$ yield. Somewhat surprisingly, phenol gave trapping only on the oxygen atom to give 41 in $36 \%$ yield, with no evidence for trapping on carbon, either C4 or C2, being observed. In the absence of any external
trapping agent, one obtains trace amounts of the triflate $\mathbf{4 m}$ and the symmetrical ether $\mathbf{4 n}$. One can also carry out a Ritter reaction, namely, treatment of 2 with triflic acid in acetonitrile as solvent to generate the acetamide 40 in $88 \%$ yield. ${ }^{14}$ This trapping would be useful for preparing analogues of memantine. Finally, we could also effect $\mathrm{C}-\mathrm{C}$ bond formation of a nonaromatic substrate, namely, trimethylsilyl acetylene, to give the acetylene product $4 p$ in $44 \%$ yield.

We also examined the addition of electrophiles other than proton to one of the exocyclic methylenes of 2 with the idea of triggering the cyclization to produce the adamantyl cation, which could then be trapped with simple nucleophiles (Table 4). Reports of such dual addition of electrophiles and

nucleophiles to similar dienes have appeared in the literature, ${ }^{15}$ but here again no systematic study has been carried out. Thus, treatment of the diene 2 with N -bromosuccinimide (NBS) in aqueous DMSO or in methanol gave the bromomethyl alcohol and methyl ether, $\mathbf{4 q}$ and $\mathbf{4 r}$, in 66 and $89 \%$ yields, respectively. Addition of either bromine or iodine to 2 in dichloromethane gave the dihalo products, $\mathbf{4 s}$ and $\mathbf{4 t}$, in yields of 88 and $77 \%$, respectively. ${ }^{8,16}$ Nonhalogenated electrophiles could also be used. Thus, addition of mercuric acetate to 2 in methanol provided the acetoxymercurio ether, which, for ease of isolation, was converted into the chloromercurio ether by addition of NaCl to give 4 u in $26 \%$ yield.

We tested the generality of this process by examining the cyclization of other substrates, namely, the three analogues of the dimethyl compound 2 with ethyl, propyl, and phenyl groups adjacent to the ketone. The additional di(exo)methylene compounds, $\mathbf{6 a - c}$, were prepared from the corresponding substituted ketones and the bis(chloromethyl)ethylene. ${ }^{6}$ Treatment of all of these three analogues $\mathbf{6 a}-\mathbf{c}$ with triflic acid in benzene afforded the expected adamantanone products $7 \mathbf{a}-\mathbf{c}$ in good yields (Scheme 1). No attempts at optimization of these yields have been made. Thus, simple alkyl and aryl substituents are well-tolerated.

The mechanism of this process (Scheme 2) would involve the addition of an electrophile, $\mathrm{E}+(\mathrm{H}+, \mathrm{X}+)$, to one of the two identical alkenes of $\mathbf{2}$ from the exo face to generate the tertiary carbocation A. Cyclization of the other alkene on to this carbocation would then generate the adamantyl cation B, despite the instability inherent in a nonplanar cation. Attack of the nucleophile on B, with loss of a proton, would afford the observed products 4. Although the formation of adamantyl cations is well-known, ${ }^{7 c, 17}$ they are often formed from adamantyl halides and not from bicyclo[3.3.1]diene systems.

We have shown that the acetamide 40 , obtained from 2 by the Ritter reaction, can be hydrolyzed to the amine 8, an analogue of memantine, in $97 \%$ yield under strongly acidic conditions (Scheme 3), i.e., conc. HCl in ethanol in a sealed tube at $100{ }^{\circ} \mathrm{C}$ for 3 days.

Scheme 3. Hydrolysis of 4 o To Give Memantine Analogue 8

In summary, we have shown that the readily available 1,5-dimethyl-3,7-dimethylene-bicyclo[3.3.1]nonan-9-one 2 can be easily converted into a wide variety of adamantanone derivatives by treatment with various electrophiles, especially proton, in the presence of a nucleophilic trapping agent. Other analogues, e.g., $\mathbf{6 a - c}$, also give the corresponding adamantanones $7 \mathbf{a}-\mathrm{c}$.

## EXPERIMENTAL SECTION

General. All reactions were carried out under an argon atmosphere unless otherwise specified. Dichloromethane was distilled from calcium hydride under an argon atmosphere. Trifluoromethanesulfonic acid of $99 \%$ purity was used. All other solvents or reagents were purified according to literature procedures. ${ }^{1} \mathrm{H}$ NMR spectra were recorded on a high-field NMR spectrometer (at 500 MHz ) and are reported relative to deuterated solvent signals. Data for ${ }^{1} \mathrm{H}$ NMR spectra are reported as follows: chemical shift ( $\delta \mathrm{ppm}$ ), multiplicity, coupling constant (Hz), and integration. Splitting patterns are designated as follows: s, singlet; $d$, doublet; $t$, triplet; $q$, quartet; $m$, multiplet; and b, broad. ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a highfield NMR spectrometer (at 125 MHz ). Data for ${ }^{13} \mathrm{C}$ NMR spectra are reported in terms of chemical shift and are reported in parts per million ( $\mathrm{ppm}, \delta$ ). Thin-layer chromatography (TLC) was carried out using precoated silica gel sheets (Merck 60 F254). Visual detection was performed using phosphomolybdic acid or iodine. Flash chromatography was performed using SilicaFlash P60 ( $60 \mathrm{~A}, 40-63$ $\mu \mathrm{m})$ silica gel with compressed air. High-resolution mass spectrometry
was taken on a quadrupole mass spectrometer equipped with a DART ion source.

General Procedure for Acid-Promoted Cyclization in Benzene. To a solution of diene $2(0.200 \mathrm{~g}, 1.05 \mathrm{mmol})$ in benzene $(5 \mathrm{~mL})$ was added trifluoromethanesulfonic acid $(0.111 \mathrm{~mL}, 1.26$ $\mathrm{mmol})$ at $0^{\circ} \mathrm{C}$. The reaction was warmed to $21^{\circ} \mathrm{C}$ and stirred for 3 h . The solution was quenched with a saturated solution of $\mathrm{NaHCO}_{3}(10$ $\mathrm{mL})$. The mixture was extracted with hexanes $(3 \times 20 \mathrm{~mL})$, and the combined organic extracts were dried with $\mathrm{MgSO}_{4}$, filtered, and concentrated in vacuo to give a crude yellow oil. Purification by flash column chromatography on silica gel (19:1 hexanes/ethyl acetate) afforded the trimethylphenyladamantanone $4 \mathrm{a}(0.253 \mathrm{~g}, 0.94 \mathrm{mmol}$, 90\%) as a light yellow oil.

General Procedure for the Triflic Acid-Promoted Cyclization and Trapping of Nucleophiles. To a solution of diene $2(0.200 \mathrm{~g}$, 1.05 mmol ) in dichloromethane ( 5 mL ) was added $m$-dimethoxybenzene $5 \mathrm{~d}(0.030 \mathrm{~mL}, 5.25 \mathrm{mmol})$ followed by trifluoromethanesulfonic acid ( $0.111 \mathrm{~mL}, 1.26 \mathrm{mmol}$ ) at $0{ }^{\circ} \mathrm{C}$. The reaction was warmed to $21^{\circ} \mathrm{C}$ and stirred for 3 h . The solution was quenched with a saturated solution of $\mathrm{NaHCO}_{3}(10 \mathrm{~mL})$. The mixture was extracted with dichloromethane $(3 \times 20 \mathrm{~mL})$, and the combined organic extracts were dried with $\mathrm{MgSO}_{4}$, filtered, and concentrated in vacuo to give a crude light yellow oil. Purification by flash column chromatography on silica gel (19:1 hexanes/ethyl acetate) afforded the 2,4-dimethoxyphenyladamantanone $4 \mathbf{d}(0.162 \mathrm{~g}, 0.49 \mathrm{mmol}, 47 \%)$ as a light yellow oil.

General Procedure for the Addition of Various Electrophiles and Subsequent Trapping of Nucleophiles. To a solution of diene $2(0.100 \mathrm{~g}, 0.525 \mathrm{mmol})$ in $1: 1 \mathrm{methanol} /$ dichloromethane ( 6 $\mathrm{mL})$ was added NBS $(0.121 \mathrm{~g}, 0.068 \mathrm{mmol})$ at $0^{\circ} \mathrm{C}$. The reaction was warmed to $21^{\circ} \mathrm{C}$ and stirred for 3 h . The solution was quenched with a saturated solution of $\mathrm{NaHCO}_{3}(10 \mathrm{~mL})$. The mixture was extracted with dichloromethane $(3 \times 15 \mathrm{~mL})$, and the combined organic extracts were dried with $\mathrm{MgSO}_{4}$, filtered, and concentrated in vacuo to give crude bromomethyl methoxyadamantanone $4 \mathbf{r}(0.140 \mathrm{~g}, 89 \%)$ as a light yellow oil.

1,5-Dimethyl-3,7-dimethylenebicyclo[3.3.1]nonan-2-one, 2. To a suspension of $60 \% \mathrm{NaH}$ in mineral oil $(0.176 \mathrm{~g}, 4.40 \mathrm{mmol})$ (washed three times with hexanes) in toluene ( 5 mL ) was added 3pentanone ( $0.086 \mathrm{~g}, 1.00 \mathrm{mmol}$ ) in toluene $(2 \mathrm{~mL})$ dropwise. A solution of 1-chloro-2-(chloromethyl)-2-propene ( $0.254 \mathrm{~g}, 2.20$ $\mathrm{mmol})$ in toluene ( 2 mL ) was added dropwise, and the reaction was refluxed overnight. The solution was then cooled to room temperature and quenched with a saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}(20 \mathrm{~mL})$. The mixture was extracted with ethyl acetate $(3 \times 20 \mathrm{~mL})$ and washed with brine $(20 \mathrm{~mL})$, and the combined organic extracts were dried with $\mathrm{MgSO}_{4}$, filtered, and concentrated in vacuo to give a crude yellow oil. Purification by flash column chromatography on silica gel (19:1 hexanes/ethyl acetate) afforded the bicyclononanone 2 ( $0.171 \mathrm{~g}, 0.90$ mmol, $90 \%$ ) as a light yellow oil.

5-Hydroxy-1,3,7-trimethyladamantan-2-one, 4j. To a solution of the diene $2(0.050 \mathrm{~g}, 0.26 \mathrm{mmol})$ in DMSO ( 1 mL ) were added conc. $\mathrm{H}_{2} \mathrm{SO}_{4}(1 \mathrm{~mL})$ and water $(0.1 \mathrm{~mL})$ at $0{ }^{\circ} \mathrm{C}$. The reaction was warmed to room temperature and stirred for 3 h . The solution was quenched with a saturated solution of $\mathrm{NaHCO}_{3}(10 \mathrm{~mL})$ and extracted with dichloromethane $(3 \times 20 \mathrm{~mL})$, and the combined organic extracts were washed with water $(10 \mathrm{~mL})$ and brine $(10 \mathrm{~mL})$, dried with $\mathrm{MgSO}_{4}$, filtered, and concentrated in vacuo to give hydroxyadamantanone $\mathbf{4 j}(0.041 \mathrm{~g}, 0.20 \mathrm{mmol}, 74 \%)$ as a light yellow oil.

5-Amino-1,3,7-trimethyladamantan-2-one, 8. To a solution of the acetamide $40(0.087 \mathrm{~g}, 0.35 \mathrm{mmol})$ and ethanol $(2 \mathrm{~mL})$ were added conc. $\mathrm{HCl}(0.5 \mathrm{~mL})$ and water $(0.1 \mathrm{~mL})$ in a sealed tube. The vessel was heated at $100{ }^{\circ} \mathrm{C}$ for 3 days. The solution was then cooled to $0^{\circ} \mathrm{C}$ and quenched with a saturated solution of $\mathrm{NaHCO}_{3}(20 \mathrm{~mL})$. The mixture was extracted with dichloromethane $(3 \times 20 \mathrm{~mL})$ and washed with brine $(20 \mathrm{~mL})$, and the combined organic extracts were dried with $\mathrm{MgSO}_{4}$, filtered, and concentrated in vacuo to give the crude 5 -aminoadamantanone $8(0.070 \mathrm{~g}, 0.34 \mathrm{mmol}, 97 \%)$ as a yellow oil.

(10) The 2-substituted isomer has one absorption at low field, $\delta 6.48$, and two absorptions at higher field, $\delta 6.01$ and 5.94 , whereas the pattern for the 3 -substituted isomer was the opposite, namely, two absorptions at low field, $\delta 6.53$ and 6.40, and one absorption at higher field, $\delta$ 6.04. For similar examples, see: von der Saal, W.; Reinhardt, R.; Stawitz, J.; Quast, H. Eur. J. Org. Chem. 1998, 1645.
