MUON CAPTURE IN OXYGEN-16

Vincent Gillet and David A. Jenkins

March 30, 1965
The muon capture rate in oxygen is used as a means for measuring the induced pseudoscalar-coupling constant \( C_P \) of weak interactions. The capture rate between the \( J^P = 0^+ \) ground state of \( O^{16} \) and the \( 0^- \), \( 1^- \), \( 2^- \), and \( 3^- \) states of \( N^{16} \) are calculated as a function of \( C_P \) with different nuclear models. Using the experimental values of the transition rates, we then determine \( C_P \). We find that the transition rate, and therefore \( C_P \), depends strongly on the nuclear model. We conclude that \( 5 < C_P/C_A < 20 \).
I. Introduction

The muon-capture interaction has gained attention because of the information which it can provide about the weak interaction. The high momentum transfer available in muon capture makes the reaction sensitive to terms in the weak-interaction Hamiltonian which are not observable in beta decay. Unfortunately, few definite conclusions can be made at present because of uncertainties in either the experiment or the interpretation of the experiment.

We propose to compute the muon capture rate in $^{16}O\mu^-$, leading to the bound states of $^{16}N$, and we will examine the sources of ambiguity in the calculation. Several authors have examined this problem. Blokhintsev and Shapiro originally suggested that the capture rate into the $J^P = 0^-$ excited state provides a measurement of $C_P$, the induced pseudoscalar coupling constant of weak interactions. Ericson, Sens, and Rood repeated the calculation and demonstrated that higher-order terms must be included. Duck has also done this calculation with the same assumption as Ericson et al., but he obtained a different result for one of the rates.

The experimental results are summarized in Table I. Figure 1 shows the four bound states in $^{16}N$ to which capture can occur from the ground state of $^{16}O$. The spin and parity of these levels are $J^P = 0^-, 1^-, 2^-$, and $3^-$. The calculated capture rates into the $0^-$ and $2^-$ states depend strongly on $C_P$, but the rates into the $1^-$ and $3^-$ levels are independent of $C_P$. As a result, the $0^-$ and $2^-$ capture rates provide a measurement of $C_P$, and the $1^-$ and $3^-$ rates should provide a test for other parts of the calculation.
II. Method of Calculation

We begin our analysis with the Hamiltonian introduced by Weinberg,

\[ H = \left( \bar{\psi}_\nu \gamma_\lambda \psi_\lambda \right) \psi_n \left[ C_V \gamma_\lambda - i C_M \sigma_{\lambda\mu} P_\mu + i C_S \frac{P_\lambda}{m_\mu} \right] \psi_p 
+ \left( \bar{\psi}_\nu \gamma_\lambda \gamma_5 \psi_\lambda \right) \psi_n \left[ i C_A \gamma_\lambda \gamma_5 - C_P \frac{P_\lambda}{m_\mu} \gamma_5 - C_T \sigma_{\lambda\mu} \gamma_5 \frac{P_\mu}{W_0} \right] \psi_p , \]

(2)

where \( C_V \) is the vector-coupling constant given by beta decay, \( C_M \) is found by comparing the weak current with the electromagnetic current, \( C_S \) is an "induced scalar" coupling constant (which has not been observed), \( C_A \) is the axial-vector-coupling constant obtained from beta decay, \( C_P \) is the pseudoscalar coupling constant, \( C_T \) is the "induced tensor" coupling constant (which has not been observed), and \( W_0 \) is the energy difference between the initial and final nuclear states. The Goldberger-Treiman relation predicts a value of about 7 for \( C_P \). Taylor estimated the corrections from high-mass states, and he concluded that \( C_P \) must be between 6.5 and 7.5 if the Goldberger-Treiman relation is valid.

Morita and Fujii use the above Hamiltonian to express the capture rate in a spherical tensor form. We have adopted their notation, and throughout our work we have used their reduction of the muon-capture problem.

The lepton part of the interaction is treated relativistically by expanding the plane-wave neutrino in a spherical representation in terms of spinors with a definite angular momentum \( \ell \),

\[ \ell = \kappa, \quad j = \ell - 1/2 \quad \text{for} \quad \kappa > 0, \]
\[ \ell = - \kappa - 1, \quad j = \ell + 1/2 \quad \text{for} \quad \kappa < 0, \]

and spin projection \( \mu \). The radial part of the neutrino wave function is given by
where \( S_\kappa \) is the sign of \( \kappa \), \( j_{\ell}(qr) \) is a spherical Bessel function, \( \ell \) is the orbital momentum corresponding to \( \kappa \), and \( \ell' \) is the orbital momentum corresponding to \(-\kappa\). The muon wave function is treated in the same representation, but it has a simple form, since the muon is assumed to be captured from the \( 1s_{1/2} \) orbit:

\[
G_{-1} = \left( \frac{Z}{a_0} \right)^{3/2} \left[ \frac{1+\gamma}{2(2\gamma+1)} \right]^{1/2} \exp(-Zr/a_0) \left( \frac{2Zr}{a_0} \right)^{\gamma-1}
\]

\[
F_{-1} = -\left( \frac{1-\gamma}{1+\gamma} \right)^{1/2} G_{-1},
\]

where

\[
\gamma = \left[ 1-(aZ)^2 \right]^{1/2}
\]

and \( F_{-1} \) is referred to as the small component of the muon wave function. These wave functions are for a point nucleus. The calculation is easily adapted to a finite nucleus by means of the wave functions of reference 9 or 10, but the correction is probably unimportant compared with the other uncertainties in the problem.

Flamand and Ford 11 found that the muon-capture rate in carbon was 6% less for a finite nucleus than for a point nucleus, and the effect in \( O^{16} \) could reduce the capture rate by as much as 10%. 12

The angular momenta (\( j \)) of the muon and neutrino are coupled to a total spin \( u \), and the orbital angular momenta (\( \ell \)) are coupled to a total spin \( v \). In
this representation, selection rules can be used for the nuclear transition. By conservation of angular momentum, one has

\[ |J_i - J_f| \leq |u| \leq |J_i + J_f| \]

For O\(^{16}\), \( J_i = 0 \), then \( u = J_f \) and the lepton system has a definite spin.

The transition rate from the ground state \( |0\rangle \) of spin \( J_i = 0 \) to the excited state \( |f\rangle \) of spin \( J_f \) and excitation energy \( W_0 (W_0 = E_f - E_0) \) is given by

\[
\lambda = 2\pi \left| \langle f|H|0 \rangle \right|^2 \text{avg} \frac{q^2 \, dq}{dE},
\]

with units \( \hbar = c = m_e = 1 \), where the matrix element is averaged over the initial states and summed over final states, \( q \) is the momentum of the neutrino, and \( dq/dE \) is a density-of-states factor,

\[
\frac{dq}{dE} = 1 - \frac{q}{m + AM}.
\]

The expression \( \langle f|H|0 \rangle \) is given by Morita-Fujii in terms of the reduced nuclear-matrix elements \( \gamma_{v\mu}^{(i)}(\kappa) \) and the coupling constants \( C^{(i)} \),

\[
\left| \langle f|H|0 \rangle \right|^2 \text{avg} = \frac{2J_i + 1}{2} \sum_{i,j} \sum_{\kappa} C^{(i)} C^{(j)} \left[ \sum_{v\mu} \gamma_{v\mu}^{(i)}(\kappa) \right] \left[ \sum_{v'\mu'} \gamma_{v'\mu'}^{(j)}(\kappa) \right],
\]

where

\[
\gamma_{v\mu}^{(i)}(\kappa) = \frac{1}{(2J_i + 1)^{1/2}} \langle f||\Xi^{(i)}||0 \rangle.
\]

is a one-body matrix element between states \( |0\rangle \) and \( |f\rangle \). The terms \( \Xi^{(i)} \) are listed in Table II with the coupling constants \( C^{(i)} \) as given by Morita-Fujii. \(^8\) New entries in this table for the induced scalar \( (C_S) \) and induced tensor \( (C_T) \) couplings have been computed by Morita and Morita. \(^{13}\) In our calculations we have used the following values for the coupling constants:
\[ C_A^\beta = -1.18 \ C_V^\beta , \]
\[ C_V = 0.972 \ C_V^\beta , \]
\[ C_A = 0.999 \ C_A^\beta , \]
\[ C_V^\beta = 1.015 \times 10^{-5}/M^2 , \]
\[ C_M = \frac{3.706 \ C_V}{2M} , \]
\[ C_S = 0, \]
\[ C_T = 0, \]

where \( M \) is the proton mass.

The term \( C_P \) is treated as a free parameter. If the vector and axial-vector currents behave properly under \( G \) conjugation, \( C_S \) and \( C_T \) are equal to zero. With our limited amount of data, we must make this assumption to simplify the calculation of \( C_P \). However, Cabibbo has shown that the \( CP \) violation recently found in \( K^0 \) decay may indicate that these terms are not zero. 14

The nuclear integration for the reduced matrix elements between states \( p \) and \( h \) gives (we use the phases of Edmond's 15)

\[
\begin{aligned}
\langle p \ | \ | \Xi^{(4)} \ | \ | h \rangle \\
\langle p \ | \ | \Xi^{(9)} \ | \ | h \rangle 
\end{aligned}
\]

\[ = \left( f_p \ | \ | \psi_{0 \nu u}^e (r) \ | \ | f_h \right) \]

\[ \times \int_0^\infty u_p \left[ g_\kappa F_{\kappa} S_{0 \nu u} (\kappa, \kappa^*) + f_{\kappa} G_{\kappa} S_{0 \nu u} (-\kappa, -\kappa^*) \right] u_h r^2 dr , \]
where the - sign refers to $i = 1$ and the + sign to $i = 9$;

$$
\langle p \mid \Pi^{(2)} \mid h \rangle = \langle \ell_p \mid \mathcal{O}_{1v}(\hat{\mathbf{r}}, \hat{\mathbf{\sigma}}) \mid \ell_h \rangle 
\times \int_0^{\infty} u_p \left[ g_{\kappa} G_{\kappa} S_1 v u (\kappa, \kappa^t) - \ell_{\kappa} F_{\kappa}, S_1 v u (-\kappa, -\kappa^t) \right] u_h r^2 \, dr.
$$

$$
\langle p \mid \Pi^{(3)} \mid h \rangle =
(-)^{3/2 + j_h + \ell_h + \ell_p + v - u} \frac{\sqrt{3}}{4\pi} \hat{\ell} \hat{p} \hat{v} \hat{u} \left\{ \begin{array}{c} \ell_p \ j_p \ \ell' \\ j_h \ \ell_h \ u \end{array} \right\} 
\times \sum_{\ell' = \ell_h + 1} \left( \begin{array}{c} v \ i \ u \\ \ell_h \ p \ \ell' \end{array} \right) \left( \begin{array}{c} \ell_p \ v \ \ell' \\ 0 \ 0 \ 0 \end{array} \right) 
\times \int_0^{\infty} u_p \left[ \ell_{\kappa} G_{\kappa}, S_1 v u (-\kappa, \kappa^t) + g_{\kappa} F_{\kappa}, S_1 v u (\kappa, -\kappa^t) \right] D_{\ell^t} u_h r^2 \, dr,
$$

where

$$
D_{\ell^t} = (-)^{\ell_h} \sqrt{3} (\ell_h + 1) \left( \frac{d}{dr} - \frac{\ell_h}{r} \right) \left[ (2\ell_h + 1)(2\ell_h + 3) \right]^{-1/2} (\ell^t_0 \ 0 \ | 10) \quad \text{if } \ell^t = \ell_h + 1
$$

and

$$
D_{\ell^t} = (-)^{\ell_h} \sqrt{3} \ell_h \left( \frac{d}{dr} + \frac{\ell_h + 1}{r} \right) \left[ (2\ell_h - 1)(2\ell_h + 1) \right]^{-1/2} (\ell^t_0 \ 0 | 10) \quad \text{if } \ell^t = \ell_h - 1
$$

are operators that act on $u_a$;
\[
\langle p \mid \Xi^{(4)} \mid h \rangle = \left( \frac{v+1}{2v+3} \right)^{1/2} \langle f_p \mid \mathcal{D}_{0v+1u} (\hat{r}) \mid f_h \rangle \delta_{v+1,u}
\]

\[
\times \int_0^\infty u_p D_+ \left[ f_+ G_{\kappa} S_{1\nu}(-\kappa, \kappa') + g_+ F_{\kappa} S_{1\nu}(\kappa, -\kappa') \right] u_h r^2 dr
\]

\[
- \left( \frac{v}{2v-1} \right)^{1/2} \langle f_p \mid \mathcal{D}_{0v-1u} (\hat{r}) \mid f_h \rangle \delta_{v-1,u}
\]

\[
\times \int_0^\infty u_p D_- \left[ f_- G_{\kappa} S_{1\nu}(-\kappa, \kappa') + g_- F_{\kappa} S_{1\nu}(\kappa, -\kappa') \right] u_h r^2 dr
\]

where \( D_+ = \frac{d}{dr} - \frac{v}{r} \) and \( D_- = \frac{d}{dr} + \frac{v+1}{r} \) are operators that act only on the lepton wave functions;

\[
\langle p \mid \Xi^{(5)} \mid h \rangle = \left( v+1 \right)^{1/2} W(11uv, 1v+1) \langle f_p \mid \mathcal{D}_{1v+1u} (\hat{r}, \vartheta) \mid f_h \rangle
\]

\[
\times \int_0^\infty u_p D_+ \left[ f_+ G_{\kappa} S_{1\nu}(-\kappa, \kappa') + g_+ F_{\kappa} S_{1\nu}(\kappa, -\kappa') \right] u_h r^2 dr
\]

\[
- v^{1/2} W(11uv, 1v-1) \langle f_p \mid \mathcal{D}_{1v-1u} (\hat{r}, \vartheta) \mid f_h \rangle
\]

\[
\times \int_0^\infty u_p D_- \left[ f_- G_{\kappa} S_{1\nu}(-\kappa, \kappa') + g_- F_{\kappa} S_{1\nu}(\kappa, -\kappa') \right] u_h r^2 dr
\]

\[
\langle p \mid \Xi^{(6)} \mid h \rangle = (-)^{f_h + 1/2}(6)^{1/2} \sum_{f_l = f_h \pm 1}^{|f_h|} \langle f_p \mid \mathcal{D}_{0\nu} (\hat{r}) \mid f_l \rangle \left\{ \begin{array}{c}
\frac{f_h}{2} \\
1
\end{array} \right\}
\]

\[
\times \int_0^\infty u_p \left[ f_+ G_{\kappa} S_{0\nu}(-\kappa, \kappa') + g_+ F_{\kappa} S_{0\nu}(\kappa, -\kappa') \right] D_{f_l} u_h r^2 dr
\]
\[ \langle p | | H^{(7)} | h \rangle \rangle = \left( \frac{v+1}{2v+1} \right)^{1/2} \left( \frac{v}{2v+1} \right)^{1/2} \langle p | | \phi_{1v+1} (r, \theta) | | \ell_h \rangle \delta_{vu} \]

\[ \times \int_0^\infty \int_0^{2\pi} u_p D_+ \left[ \int_0^\infty G_k S_{0vu} (\kappa - \kappa') \pm g_k F_k S_{0vu} (\kappa, -\kappa') \right] u_h r^2 dr \]

where the + sign refers to i=7 and the - sign to i=8. The symbols p and h indicate the \( l_s j \) quantum numbers for the respective state. Here \( u_p \) and \( u_h \) are harmonic oscillator wave functions,

\[ u_{n, l} (r) = N b^{-3/2} P(r) r^l e^{-1/2(r/b)^2}, \]

where \( N \) is a normalization constant

\[ N = \frac{1}{\pi^{1/4}} \left( \frac{2^{n+l+1}}{(2n+2l+1)!} \right)^{1/2}, \]

\( b \) is the oscillator length parameter, and

\[ P(r) = 1 \quad \text{for} \quad n = 1, \]

\[ = \frac{2l+1}{2} - \left( \frac{r}{b} \right)^2 \quad \text{for} \quad n = 2, \]

\[ = \frac{1}{2} \left[ \frac{(2l+3)(2l+5)}{4} - (2l+5) \left( \frac{r}{b} \right)^2 + \left( \frac{r}{b} \right)^4 \right] \quad \text{for} \quad n = 3. \]
We use the reduced matrix elements
\[
\langle l_p | \mathcal{O}_{0vu}(\hat{\tau}) | l_h \rangle = \frac{1/2+j_h+u}{4\pi} \hat{j_h} \hat{l_p} \hat{l_h} \hat{u} \begin{pmatrix} l_p & j_p & 1/2 \\ j_h & l_h & u \end{pmatrix} \begin{pmatrix} l_p & u & l_h \\ 0 & 0 & 0 \end{pmatrix},
\]
\[
\langle l_p | \mathcal{O}_{1vu}(\hat{\tau},\sigma) | l_h \rangle = (-)^{4+j_p+l_p} \frac{3}{2\sqrt{2} \pi} \hat{l_p} \hat{j_p} \hat{l_h} \hat{v} \hat{j_h} \hat{j_p} \hat{u}.
\]
\[
\times \begin{pmatrix} l_p & v & l_h \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l_p & l_h & v \\ 1/2 & 1/2 & 1 \\ j_p & j_h & u \end{pmatrix},
\]
\[
S_{kvu}^{(\kappa, \kappa')} = \sqrt{2} \hat{l} \hat{j} \hat{l} \hat{v} \hat{j} \hat{v} \begin{pmatrix} l & l' & v \\ j & j' & u \end{pmatrix} \begin{pmatrix} 1/2 & 1/2 & k \end{pmatrix},
\]
where \( \hat{j} = (2j+1)^{1/2} \), and we have set \( \kappa' = -1 \).
A calculation of $C_P$ requires a good knowledge of the nuclear wave function. The purpose of our work is to determine the uncertainty in the computation of $C_P$ due to uncertainties of the nuclear wave functions coming from the nuclear problem itself, which is only approximately solved. Three nuclear models are used:

(a) the independent-particle model (IP),
(b) the diagonalization of the residual interaction in the subspace of the $1\hbar\omega$ particle-hole excitations (approximation I),
(c) the random-phase approximation (approximation II).

The particle-hole wave function of the excited state is of the form

$$|f\rangle = \sum_{m_p m_h}^J X_{ph}^{J} (j^+_p h^+ m_p m_h | J^M) \xi^+_p m_p \xi^+_h m_h | 0\rangle. \quad (9)$$

The ket $|0\rangle$ is the Hartree-Fock ground state and $X_{ph}^{J}$ are the configuration mixing coefficients associated with the particle-hole configurations (ph). Their normalization is

$$\sum_{ph} (X_{ph}^{J})^2 = 1.$$

The associated "quasi-particle" operators $\xi^+, \xi$ are related to the true particle operators $\eta^+, \eta$ through the transformation$^{16}$

$$\xi^+_p m_p = \eta^+_p m_p,$$
$$\xi^+_h m_h = (-)^{m_h} \eta^{+m_h}_h - m_h.$$

We have used particle-hole amplitudes computed by two different groups, and we must therefore be careful to use the proper phase conventions. In reference$^{19}$ the tabulated amplitudes $X_{ph}^{J}$ differ from the above choice of phases by a factor
The phases of Elliott and Flowers differ from the above because of their use of (i) the Condon and Shortley convention for the spin and orbital-angular-momentum coupling order (slj), (ii) a 2s harmonic oscillator wave function which is negative near the origin, and (iii) the opposite coupling order in their particle-hole amplitudes.

The one-body operator for absorption of a multipole radiation $\lambda$, accompanied by the jump of a nucleon from the single-particle state $\alpha$ to state $\beta$, is

$$\Xi^\lambda_\mu = \sum_{\alpha\beta} \langle \alpha | \Xi^\lambda | \beta \rangle (2\lambda + 1)^{1/2} (-)^{j_\beta - m_\beta} \tag{10}$$

where $\langle \alpha | \Xi^\lambda | \beta \rangle$ is a one-body reduced matrix element.

With the definitions (9) and (10) the transition matrix element in approximation I is

$$\langle f | \Xi^\lambda_\mu | 0 \rangle = \delta_{j_f, \lambda} \delta_{M_\mu} \sum_{\text{ph}} X_{\text{ph}}^{j_f} \frac{\langle p | \Xi | h \rangle}{(2j_f + 1)^{1/2}}.$$ 

This expression reduces to one term in the independent-particle model (IP), for which $X_{\text{ph}} = 1$.

In approximation II (RPA), one has also to take into account the probability amplitude $Y_{\text{ph}}^{j_f}$ for exciting the nuclear state $| f, J_f M_f \rangle$ by annihilation of a particle-hole pair (ph) in the ground state. The expression for the transition matrix element is then

$$\langle f | \Xi^\lambda_\mu | 0 \rangle = \delta_{j_f, \lambda} \delta_{M_\mu} \frac{1}{(2j_f + 1)^{1/2}} \sum_{\text{ph}} \left\{ X_{\text{ph}}^{j_f} \langle p | \Xi | h \rangle + Y_{\text{ph}}^{j_f} \langle h | \Xi | p \rangle \right\}.$$
The normalization of the amplitudes in this case is

\[
\sum_{ph} \left\{ \left( \frac{x}{y} \right)^2 - \left( \frac{y}{x} \right)^2 \right\} = 1.
\]

Then the reduced matrix elements of Eq. (8) are given by

\[
\langle f | \Xi^{(i)} | 0 \rangle = \sum_{ph} X_{ph}^{(f)} \langle p | \Xi^{(i)} | h \rangle
\]

\[
+ \gamma \sum_{ph}^{(f)} \langle h | \Xi^{(i)} | p \rangle.
\]  

The wave functions for the \( N^{16} \) bound states are taken from the wave functions for the analogous levels in \( O^{16} \) under the assumption of good isospin.

In approximation I we use wave functions derived from two different potentials. The first potential is the Rosenfeld mixture used by Elliott and Flowers, \( 18 \) and the second potential is found from a least-squares search carried over nine energy levels of \( O^{16} \) by Gillet and Vinh Mau. \( 17 \) Wave functions are derived from the potentials by finding the set of basis vectors \( \psi \) for which the matrix \( \langle \psi_\alpha | V | \psi_\beta \rangle \) is diagonal. Since two values of the potential \( V \) were used in these two analyses, two different wave functions are obtained. Both potentials, with strongly different characteristics as seen from Table III, give similar overall good fits for the energies. However, the different potentials affect the small components of the nuclear wave function appreciably, as shown in Table IV, allowing a numerical discussion of the uncertainties due to the nuclear parameters.

For the purpose of this paper, it is important to note in Table IV the difference in sign of the small component of the \( 0^- \) wave function. As will be shown later, the capture rate and the value of \( C_P \) are very sensitive to this component. We have a preliminary report of a third calculation of the \( 0^- \) wave function made
by Lewis. He obtains an amplitude of $-0.07$ for the $2s_{1/2}(1p_{1/2})^{-1}$ component of the $0^-$ wave function as compared with Gillett's amplitude of $+0.055$. However, Lewis used a Serber force, and this would be expected to give a somewhat different result.

IV. Results

The reduced matrix elements $\gamma_{1\nu}^{(i)}$ were calculated on an IBM-7094 computer to allow the use of numerical methods to evaluate the radial integrals. In checking our method, we first calculated the muon-capture rate in $C^{12}$ to the ground state of $B^{12}$ in order to compare our result with the Morita and Fujii calculation. Because of ambiguities in the nuclear wave function, the computed capture rate does not agree with the rate determined experimentally. Morita and Fujii correct this by taking a ratio with the inverse-beta-decay transition, and obtain for the capture rate

$$\lambda^\mu_{\exp} = \frac{\lambda^\mu_{\text{calc}}}{\lambda^\beta_{\text{calc}}} \lambda^\beta_{\exp}, \quad (12)$$

where $\lambda^\mu_{\text{calc}}$ is the muon-capture rate calculated with the Morita-Fujii method, and $\lambda^\mu_{\exp}$ is the observed rate. Using

$$\lambda^\beta_{\exp} = 33.15 \text{ sec}^{-1} \quad \text{and} \quad \lambda^\beta_{\text{calc}} = 159 \text{ sec}^{-1},$$

and an oscillator length parameter $b = 1.59 F$, we obtain the results given in Fig. 2, which shows $\lambda^\mu_{\exp}$ as a function of $C_P/C_A$ and the experimental value of $6750^{+300}_{-750} \text{ sec}^{-1}$ measured by Maier et al. From the graph we would conclude $10 < C_P/C_A < 30$, where we have not allowed for errors in the nuclear wave function.
The capture rate $\lambda_{\text{calc}}^\mu$ has been computed by Morita with his method in which the small components of the muon wave function are set equal to zero. With the small component, we obtain a transition rate of $35.0 \times 10^3 \text{ sec}^{-1}$, which compares to the value $34.2 \times 10^3 \text{ sec}^{-1}$ of Morita and Fujii. This good agreement provides a check on our computer program.

We now compute the transition rates in $^{16}O$, and in Table V we compare the theoretical transition rates, using the wave functions $I_B^\mu$ of Table IV with and without the small relativistic component of the muon wave function. This component has been neglected in earlier calculations. The small component affects the transition rate by only a few percent, which is insignificant when compared with the other sources of uncertainty discussed in the following sections. Nevertheless, the small component is included in the following results.

The oscillator-length parameter $b$ that enters into the oscillator-well-wave functions is, in principle, given by an analysis of the elastic electron-scattering data, i.e., $1.75 \, F$ for $^{16}O$. In Table VI we show the results of varying the $^{16}O$ oscillator length by 15% while using the wave functions of case $I_G$. A 10% change in $b$ produces about a 10% change in the $0^-$ transition rate for $C_P/C_A \approx 8$.

The transition rates for different nuclear models and $b = 1.75 \, F$ are tabulated in Table VII. As one would expect for the almost pure states considered here, the transition computed with approximation II (RPA) and approximation $I_B^\mu$ differ only slightly, as shown in columns $I_B^\mu$ and II. The agreement in the $2^-$ and $3^-$ transition rates for the $I_A$ and $I_B$ wave functions shows that these rates are not very sensitive to the small components of the wave functions, which are rather different (Table IV).

In Fig. 3 we show the $0^-$ transition rate as a function of $C_P$ for three nuclear models. The wave functions for the three cases are given by
\( \psi_{IP} = |1 p_{1/2}^{-1} 2 s_{1/2} \rangle \),

\( \psi_A = 0.99 |1 p_{1/2}^{-1} 2 s_{1/2} \rangle - 0.05 |1 p_{3/2}^{-1} 1 d_{3/2} \rangle \),

\( \psi_B = 0.99 |1 p_{1/2}^{-1} 2 s_{1/2} \rangle + 0.055 |1 p_{3/2}^{-1} 1 d_{3/2} \rangle \),

where \( \psi_{IP} \) represents the independent-particle model, \( \psi_A \) is the Elliott and Flowers wave function, and \( \psi_B \) is the Gillet and Vinh Mau wave function. The only difference between \( \psi_A \) and \( \psi_B \) is in the sign of the small component of the wave function. As shown in Fig. 3, a variation in the small component produces large differences in the \( 0^- \) transition rate. The sensitivity of the transition rates to the small component is to be expected, since the small amplitude multiplies large one-body matrix elements in Eq. (11). Furthermore, the sensitivity is enhanced by the cross terms between large and small components in the expression for the transition rates of Eqs. (5) and (7).

Although the \( 3^- \) transition is third forbidden, its rate is 5% of the \( 1^- \) case, which is first forbidden. The high-momentum transfer in muon capture makes the forbidden transitions more important than in beta decay, for which the comparable forbidden transitions would be negligible.
V. Comparison with Earlier Work

It is interesting to look at the earlier works and compare them with our results. Beltrametti and Radicati have computed the matrix elements for capture in $^16O$, but they do not present the transition rates. Duck does not present his rates for the $0^+ \rightarrow 0^-$ transition, but he computes $0^-/1^-$, the ratio of the $0^+ \rightarrow 0^-$ transition to the $0^+ \rightarrow 1^-$ transition. It is difficult to compute the $0^+ \rightarrow 0^-$ transition from data given in Duck's paper, since there are disagreements in sign in the two publications of his work (e.g., see the phases of the wave functions and definitions of the coupling constants given in these two references). However, we can compare calculations by computing the $0^-/1^-$ ratio, using the Morita-Fujii method. Table VIII compares the results of Duck and of Ericson et al. with our work. Our numbers are much higher than those of Duck, but we agree within 10% with Ericson et al. Our agreement with Ericson et al. is also good when we compare the absolute rates shown in Table IX. The small disagreement could be attributed to a different treatment of the lepton problem and the use of slightly different coupling constants. The discrepancy with Duck's work is not understood.

VI. Analysis of Calculation

A measurement of the $0^+ \rightarrow 0^-$ transition rate does not determine $C_P$ uniquely. Figure 4 shows the transition rate as a function of $C_P$ for nuclear model $I_G$, and there are two values of $C_P$ which give agreement with the experimental value. When the $C_{12}$ data given in Fig. 2 are used, the higher value can be excluded. The transition rate into the $0^-$ state is very sensitive to the small component of the nuclear wave function; as a result, we cannot accurately compute $C_P$ until the nuclear wave functions are known more accurately. Also, the two experimental measurements of the $0^-$ rate are outside each other's experimental error. From our analysis of
the experimental data for capture into the $0^-$ state, we conclude $5 < \frac{C_P}{C_A} < 20$, as shown in Fig. 3. This agrees with the theoretical value of $\frac{C_P}{C_A} \approx 7$ predicted by Goldberger and Treiman. The results are valid only if the induced pseudotensor term $C_T$ is zero, because the introduction of another unknown, $C_{T'}$, would lead to more doubtful conclusions in the present state of the experimental evidence and of the nuclear model.

The disagreement between theory and experiment for capture into the $1^-$ and $2^-$ states can probably be attributed to the many admixtures present in the wave functions. As shown for the $0^-$ rate, which has only one small component, transition rates are very sensitive to the small admixtures. No conclusions can be drawn from the $1^-$ transition, since the rates computed by the Elliott and Flower wave functions disagree strongly with the rate computed from the Gillet and Vinh Mau wave functions, and both rates are higher than the experimental value. The $2^-$ transition rate does not seem to depend strongly on the nuclear model, and two calculations of this rate are in fair agreement. However, the computed rate does not agree with experiment for any value of $C_P$. As $C_P$ is increased, the computed rate goes through a minimum of $1.2 \times 10^4$ sec$^{-1}$ for $\frac{C_P}{C_A} \approx 22$, but this value is still higher than the measured value of $0.63 \times 10^4$ sec$^{-1}$.

The $3^-$ transition rate is so small that it has not been observed yet. However, it does not depend on $C_P$, so a measurement would provide a check of the wave function.
VII. Conclusions

We have computed $C_P$, the pseudoscalar coupling constant, from the muon capture rate in $^{16}O$. The calculation does not give a precise value of the pseudoscalar coupling constant because of the uncertainties in the nuclear wave function and the muon interaction. Several things can be done to improve the situation. First, an accurate nuclear wave function must be found for $^{16}N$. Cabibbo has suggested that the amplitude for the small components could be found by using the wave functions to compute the electromagnetic transitions in $^{16}N$. With an accurate wave function, the coupling constant should be easy to find from this transition rate. Next, there is the question of the induced pseudotensor and pseudoscalar coupling constants. At present there are not enough experimental data to justify a search for these terms, and we must assume that they are zero to simplify the calculations. However, if they are present they could seriously affect the calculation of muon-capture rates. Thus far, most calculations for muon-capture rates have used a free parameter $C_P$ and the other possible parameters $C_S$ and $C_T$ have been neglected. The absence of these terms could be ascertained by observing muon-capture transitions in which their matrix elements would be large compared with other terms in the Hamiltonian. For instance, a $0^+\rightarrow0^+$ transition would be useful for finding the $C_S$ term because the axial-vector part of the Hamiltonian cannot contribute to the transition.

In gathering more experimental data, one must be careful to measure the muon-capture rates in those nuclei with wave functions that are reasonably well known. For this reason, the transitions $^{24}Mg\rightarrow^{24}Na\ast$ and $^{48}Ti\rightarrow^{48}Sc\ast$ have been suggested by Rasmussen. Using the Nilsson model, Mang has developed wave functions for $^{24}Mg$, and McCullen et al. have published wave functions for $^{48}Ti$. At present the $^{24}Mg\rightarrow^{24}Na$ transition looks most promising, because the excited
states in Na$^{24}$ are well known and these states must be known before an experiment can be planned to measure the transition rate. The Ti$^{48}$ → Sc$^{48}$ transition is experimentally difficult at the moment because of the uncertainty in the excited states of Sc$^{48}$. There has been very little experimental investigation of Sc$^{48}$ even though the energy levels have been predicted by McCullen et al. $^{27}$ and the spins of the levels have been predicted by Rasmussen. $^{28}$ If the highest excited states of Sc$^{48}$ have $J^P = 0^+$ and $1^+$, as indicated by Rasmussen, this nucleus may be useful for a muon-capture experiment.

Another approach for obtaining the coupling constants has been suggested by Foldy and Walecka. $^{29}$ They obtain the nuclear matrix elements empirically from electron scattering data, and thereby avoid the uncertainties inherent in obtaining the nuclear wave functions from energy levels. They have used this approach to compute the coupling constants from the total capture rates, i.e., the capture into all final states; but they found that these rates are not sensitive to the coupling constants. However, this technique could be very useful in computing the partial transition rates, which are sensitive to the coupling constants, as we have shown.
Acknowledgments

The authors wish to thank Professor John Rasmussen and Professor Emilio Segrè for their support. We thank Dr. M. Morita for assisting in checking our calculations and Dr. Torlief Ericson for informing us of his results. One of us (V. G.) wishes to thank the Nuclear Chemistry Department at the Lawrence Radiation Laboratory for its hospitality. We also thank the Computer Group at the Lawrence Radiation Laboratory for the time they made available on the IBM-7094.
Appendix

Detail of the Calculation of the Transition Rate

The calculation of the capture rate into the 0^- state of N^{16} begins with the evaluation of the matrix elements \( \langle p | \Xi^{(1)} | h \rangle \). Using the nuclear model \( I_B \), we evaluate these matrix elements for the particle-hole pairs \( 2s_1/2 \rightarrow 1p_1/2 \) and \( 1d_3/2 \rightarrow 1p_3/2 \). With \( u = 0 \), \( v = k \), and \( \kappa = 1 \), the nonzero matrix elements are

\[
\langle 2s_{1/2} | H^{(2)} | 1p_{1/2} \rangle = \langle 2s_{1/2} | H_{110}^{(2)} \rangle = \langle 1p_{1/2} \rangle
\]

\[
\times \left[ S_{110}(1, -1) \int_0^\infty u_2, 0 g_{14} G_{-1} u_1, 1 r^2 dr \right]
\]

\[
- S_{110}(-1, +1) \int_0^\infty u_2, 0 f_{14} F_{-1} u_1, 1 r^2 dr \right].
\]

Using \( b = 1.75 \) fm, \( q = 93.5 \) MeV/c, and the Hermite-Gauss numerical integration procedure, we obtain

\[
\langle 2s_{1/2} | H^{(2)} | 1p_{1/2} \rangle = \left( \frac{3}{8\pi^2} \right)^{1/2} \left[ - \left( \frac{2}{3} \right)^{1/2} (-8.01) - \left( \frac{2}{3} \right)^{1/2} (0.181) \right]
\]

\[= + 1.25;\]

in the same way we compute

\[
\langle 1d_{3/2} | H^{(2)} | 1p_{3/2} \rangle = \left( \frac{\sqrt{3}}{2\pi} \right)^{1/2} \left[ - \left( \frac{2}{3} \right)^{1/2} (14.68) - \left( \frac{2}{3} \right)^{1/2} (-0.840) \right]
\]

\[= - 3.11,\]
\begin{align*}
\langle 2s_{1/2} | H^{(6)} | 1p_{1/2} \rangle &= (-1)^{1/2+1/2} (6)^{1/2} \sum_{l^1=0,2} \langle 0 | \hat{D}_{000}^{(2)} | l^1 \rangle \\
&\times \left\{ \begin{array}{ccc}
1/2 & 1/2 & \ell^1 \\
1 & 1 & 1/2
\end{array} \right\} \left[ S_{000}^{(2)}(-1, -1) \int_0^\infty u_{2, 0} \hat{G}_{-1} D_{\ell^1} u_{1, 1} r^2 dr \\
+ S_{000}^{(1, 1)} \int_0^\infty u_{2, 0} \hat{G}_{-1} D_{\ell^1} u_{1, 1} r^2 dr \right]
\end{align*}

D_2 = (2)^{1/2} \left( \frac{d}{dr} - \frac{1}{r} \right)

D_0 = - \left( \frac{d}{dr} + \frac{2}{r} \right)

\begin{align*}
\langle 2s_{1/2} | H^{(6)} | 1p_{1/2} \rangle &= (6)^{1/2} \left( \frac{1}{8\pi^2} \right)^{1/2} \frac{1}{(6)^{1/2}} \left[ \sqrt{2} (-7996) + (-\sqrt{2})(66.1) \right] = -1283

\langle 1d_{3/2} | H^{(6)} | 1p_{3/2} \rangle &= (-1)^{1+1/2+3/2} (6)^{1/2} \left( \frac{1}{2\pi} \right)^{1/2} \frac{1}{2\sqrt{3}} \left[ \sqrt{2} (-1.38 \times 10^4) + (-\sqrt{2})(231) \right] = +2233,
\end{align*}
\[
\langle 2s_{1/2} \mid \Xi^{(7)} \mid 1p_{1/2} \rangle = \langle 2s_{1/2} \mid \rho_{110}(\hat{r}, \varphi) \mid 1p_{1/2} \rangle \\
\times \left[ S_{000}(-1, -1) \int_0^\infty u_2, 0 D_{+1} G_{-1} u_{1,1} r^2 dr \right. \\
+ \left. S_{000}(1, 1) \int_0^\infty u_2, 0 D_{+1} G_{-1} u_{1,1} r^2 dr \right] \\
= \left( \frac{3}{8 \pi^2} \right)^{1/2} \left[ \sqrt{2} (1535) + (-\sqrt{2}) (-3.83) \right] \\
= 424.2,
\]

\[
\langle 1d_{3/2} \mid \Xi^{(7)} \mid 1p_{3/2} \rangle = \frac{\sqrt{3}}{2 \pi} \left[ \sqrt{2} (-3034) + (-\sqrt{2}) (-29.6) \right] = -1171,
\]

\[
\langle 2s_{1/2} \mid \Xi^{(8)} \mid 1p_{1/2} \rangle = \left( \frac{3}{8 \pi^2} \right)^{1/2} \left[ \sqrt{2} (1535) - (-\sqrt{2}) (-3.83) \right] = 422.1,
\]

\[
\langle 1d_{3/2} \mid \Xi^{(8)} \mid 1p_{3/2} \rangle = \frac{\sqrt{3}}{2 \pi} \left[ \sqrt{2} (-3034) - (-\sqrt{2}) (-29.6) \right] = -1194.
\]

From Table IV we find

\[ X_{2s \ 1p} = 0.999, \]

\[ X_{1d \ 1p} = 0.055. \]

Using Eqs. (8) and (11), we compute

\[
\gamma^{(2)} = \langle f \mid \Xi^{(2)} \mid 0 \rangle \\
= (0.999) (1.25) + (0.055) (-3.11)
\]
Letting \( C_p = 7 C_A \), we obtain for the coupling constants in natural units:

\[
\begin{align*}
C^{(2)} &= 3.55 \times 10^{-12}, \\
C^{(6)} &= -1.93 \times 10^{-15}, \\
C^{(7)} &= 5.58 \times 10^{-16}, \\
C^{(8)} &= -3.91 \times 10^{-15}.
\end{align*}
\]

These matrix elements and coupling constants are substituted into Eq. (7) to give:

\[
\left| \frac{\langle f | H | 0 \rangle}{\text{avg}} \right|^2 = 1.17 \times 10^{-23}.
\]

With a value of \( q = 183 \) (natural units), we find the transition rate from Eq. (5) to be:

\[
\lambda = (2\pi) (1.17 \times 10^{-23}) (183)^2 (0.994) \frac{1}{1.288 \times 10^{-21}}
\]

\[
= 1.90 \times 10^3 \text{ sec}^{-1},
\]

where we have used \( \hbar/\text{m}_e c^2 = 1.288 \times 10^{-24} \text{ sec} \).

Table VI. Effect of the variation of the oscillator-length parameter. Columns 1, 2, and 3 correspond to $b = 1.59, 1.75, 1.96 \text{ F}$, respectively. The central value is the one obtained from elastic-electron-scattering data. The wave functions used are the ones of case $I_B$ of Table IV.

Table VIII. Comparison of the transition-rate ratio, $0^-/1^-$, with oscillator length $b = 1.56 \, \text{F}$ and with the Elliott and Flower wave functions. The muon wave function is set equal to an average value in the radial integral, and $F$, the small component of the muon wave function, equals zero.
