Abstract

The validity of the nuclear track emulsion technique for fast-neutron dosimetry is examined in the exposure of a human phantom to PuBe neutrons. Semiautomatic track scanning and high-speed data analysis obviate the major disadvantages of emulsion dosimetry, and allow the absolute differential proton track energy spectrum, at various locations in the phantom to be obtained without a serious cost in time. From this are calculated the total absorbed local tissue dose due to proton recoils and the local thermal neutron intensity during irradiation.
NEUTRON DOSIMETRY IN AND AROUND HUMAN PHANTOMS
BY USE OF NUCLEAR TRACK EMULSION
Studies with Plutonium-Beryllium Neutrons

I. INTRODUCTION

Nuclear track emulsion has been widely used for detection and measurement since the beginning of neutron research. However, health physicists have not until now shown much interest in this tool, which is probably the best single neutron dosimeter. The reason for this lack of interest is simple: track scanning and analysis require a great deal of time. Now semi-automatic scanning of emulsions and data analysis by electronic computer have partly overcome this difficulty. But the question arises — "How good is this tool for analyzing and evaluating tissue dose from neutron exposure?"

In an attempt to answer this question, nuclear track emulsion was exposed in and around human phantoms to various kinds of neutrons. In this report we present data obtained from exposure to plutonium-beryllium neutrons. These data include the absolute differential energy spectra, average energy, and emulsion dose of proton tracks at various depths in the phantom. From this the tissue dose is calculated.
II. EXPERIMENTAL METHOD

The nuclear emulsions (Ilford L.4 and Kodak NTA) were exposed by the PuBe source, in a wooden room, 4m x 5m x 3m high, in and around the human phantom, details of which are shown in Figs. 1 and 2. Tracks in the developed emulsions were scanned and analyzed.

Neutron source

LRL source PuBe #593 was used. It is a cylinder, 1.30 in. o.d. x 3.69 in. high, containing 80 g of plutonium. The total emission rate was $5.89 \times 10^6$ n/sec.

Nuclear emulsions

Ilford L.4 600-micron emulsions were cut into four pieces (25 x 19 mm or 1 x 3/4 in.) from an original piece (1 x 3 in.), and each was wrapped with black paper and black tape. Each emulsion was sealed in a 20-mil polyvinyl packet with Kodak NTA type film. Each packet was so oriented that the emulsions were exposed normal to the source, which was 50 cm from the center of the phantom.

Phantom

The human phantom was a right elliptical cylinder, 20 x 36 cm by 60 cm high made of 0.65-cm polyethylene (Figs. 1 and 2) and filled with tissue-equivalent fluid.* It stood on a support 76 cm above the floor. Six polyvinyl

* Tissue-equivalent fluid:

\[ \begin{align*}
H_2O, & \quad 75 \text{ lb;} \\
\text{urea}, & \quad 9.46 \text{ lb;} \\
\text{sucrose}, & \quad 24.7 \text{ lb;} \\
\text{cresol}, & \quad 1.05 \text{ lb.}
\end{align*} \]
packets of films (C-1 through C-5, and C-9) were kept during the exposure on the mid-horizontal plane of the phantom with a thin plastic plate. Figure 2 shows the locations of these packets.

Developing and fixing

After the exposure of 87 hours and 20 minutes, the L.4 films were opened in a darkroom and were measured for thickness and lateral extent. They were then developed and fixed by a modified cold-cycle process in which the solutions were kept at 5°C. To reduce thickness shrinkage, the processed emulsions were soaked in a concentrated solution of wood rosin in ethanol (35 g per 100 ml) for 24 hr. Emulsion history charts (Fig. 3) were kept for each film. The thickness and lateral extent of the processed films were remeasured and the shrinkage factors $f_1$ and $f_2$ were calculated for each emulsion. Prior to scanning, films were mounted on 1 x 3 in. micro-slides with clear epoxy cement.

The NTA films were developed according to the usual method.

*A modified cold-cycle process:

45 min water (presoak)
90 min developer: Na$_2$SO$_3$, 3.6 g; Na$_2$S$_2$O$_5$, 0.5 g; 10% KBr solution, 4.4 ml; Amidol, 1.6 g; H$_2$O, 500 ml
45 min stop bath: HAc, 1 ml; H$_2$O, 500 ml
18 hr fix: Na$_2$S$_2$O$_3$, 150 g; Na$_2$S$_2$O$_5$, 11.2 g; H$_2$O, 500 ml
4 hr water (dilution and washing)
3 hr EtOH (to dry): gradual dilution to 100% EtOH
24 hr rosin (soak)
2 hr air (to dry between silk)
Scanning

The Ilford films were scanned by use of the three-axis digitized microscope and apparatus in Figs. 4 and 5. The date, the relative humidity at the time of scanning, the emulsion number, and the end-point coordinates of two tracks were recorded on each punched card. The microscope was fitted with a 65× oil-immersion objective and 10× wide-field eyepieces. It required 5 hr to scan 900 tracks.

The emulsions were exposed so that each contained $10^5$ to $10^6$ proton tracks. We obtained a 900-track sample from each by taking a microscopic "random walk" through an emulsion, seeking out the track ending nearest to the end point of the previous track. This technique allows rapid scanning, but introduces a sampling bias against short tracks; a correction for this bias is made later, however. Only tracks that had both end points within the emulsion were recorded; i.e., the hydrogen in the emulsion served as an internal radiator, and was the sole source of accepted proton recoils.

Analysis of tracks in nuclear emulsions

The punched cards were analyzed by an IBM-650 Computer with a special computer program called "RECOIL I." This program is designed to calculate the proton recoil energy spectrum in nuclear emulsion exposed to neutrons. The following conditions apply to "RECOIL I."

a. The emulsion must be of 625 microns nominal initial thickness.

b. The emulsion must be of "standard" composition, i.e., density ≈ 3.8 at 50% relative humidity and 20°C.

c. The input tracks scanned must be a random sample of the tracks present in the emulsion, or a suitable correction must be made.

d. The exposure must be roughly isotropic.
The input to RECOIL I consists of rectangular coordinates \((x_1, y_1, z_1, x_2, y_2, z_2)\) for the beginning and end points of a track measured in the emulsion. For each track a correct length in microns is computed,

\[
\ell = \left( f_1^2 \Delta x^2 + f_1^2 \Delta y^2 + f_2 \Delta z^2 \right)^{\frac{1}{2}}
\]

where \(\ell\) is the length of the track, \(f_1\) is the correction factor for the lateral \((x,y)\) shrinkage, and \(f_2\) is a correction containing the thickness \((z)\) shrinkage factor. The \(\Delta x\) -- i.e., \((x_1 - x_2)\) -- and \(\Delta y\) -- i.e., \((y_1 - y_2)\) -- are in units of microns, but \(\Delta z\) is in units of 0.60 micron. Therefore the correction \(f_2\) is the product of 0.60 \times the \(z\) shrinkage factor. The program compares the computed length with a range-energy table for protons in nuclear emulsion (Fig. 6), and the track is sorted into one of 85 energy intervals. Several hundred tracks thus generate the points of a raw proton-recoil energy spectrum.

RECOIL I corrects the raw proton spectrum by a function based on geometry. This function gives the probability that a track of a given length which originates in the emulsion will end in the emulsion. Using 625 \(\mu\) for the emulsion thickness at exposure, and assuming an infinite lateral extent for the emulsion (although the actual size is as small as a 2.0-cm square), we find this function for isotropic exposure is

\[
P = \frac{625 - 0.5\ell}{625} \quad \text{for} \quad \ell < 625 \text{ microns},
\]

and

\[
P = \frac{312}{\ell} \quad \text{for} \quad \ell > 625 \text{ microns}.
\]

These equations are derived in the Appendix, as well as those for "face-normal" exposure. The exposure of the experimental emulsions in and around the phantom was somewhere between the face-normal and isotropic...
cases; but since Fig. 7 reveals that the correction is very nearly the same, we used the isotropic correction.

Each point on the spectrum is also corrected by its energy interval. RECOIL I thus computes 85 proton-recoil spectrum points \( \frac{\Delta N}{P \Delta E} \) and the standard deviation \( \frac{\sqrt{\Delta N}}{P \Delta E} \) for each point, where \( \Delta N \) is the number of tracks in energy interval \( \Delta E \) and \( P \) is the geometry correction. In addition, the track density in the L.4 films was independently measured by counting the number of tracks (in depth) from 6 to 28 fields of view. The volume per field was \( 3.34 \times 10^{-5} \) cm\(^3\).

The number of tracks in depth per field of view for NTA was measured by the standard method. The field was 0.00060 cm\(^2\) when 450\(\times\) magnification was used.

### III. RESULTS

The proton-recoil energy spectra in and around the human phantom, as computed from tracks scanned in Ilford L.4 emulsions C-1 through C-5 and C-9, are given in Table 1. The values shown are \( \frac{\Delta N}{P \Delta E} \) normalized to give \( \Sigma \frac{\Delta N}{P \Delta E} = 10,000 \). The normalization allows direct comparison of the spectra, channel by channel. These values, converted to give the absolute differential proton track spectra found in the emulsions, are plotted in Figs. 8 through 12. Superimposed on each plot is the proton recoil energy spectrum of the 80-g PuBe source as recorded in emulsions C-9 and C-14 exposed in air at 50 cm. The neutron spectrum to which the phantom was exposed is given in Fig. 13 and is based on analysis of 10,000 tracks in emulsion C-14. In each case the actual data points are given, but the line through the points has been corrected for the sampling bias by the empirically determined factor

\[ f = 0.44 E^{-2.3}, \quad \text{where} \quad E = 0.4 \text{ to } 0.66 \text{ MeV}. \]
There is no sampling correction for tracks of energy greater than 0.66 MeV, and it is assumed that the proton spectra are constant below 0.4 MeV. The sampling-correction factor is based on analysis of proton recoil spectra obtained from emulsions exposed to monoenergetic neutrons of energy 0.5 to 5 MeV. The assumption that the proton spectra are constant below 0.4 MeV seems justified by the extensive measurements by de Pangher on the PuBe neutron spectrum, which rule out a large number of low-energy neutrons.

Table 2 lists the proton track data obtained from the Ilford emulsions. These include the air-equivalent neutron exposure at the point of interest in the phantom, and the % of the tracks lost in the region 0 to 0.66 MeV by sampling inefficiency and bias. The measured track densities are corrected for this to yield the corrected track density per unit exposure, average proton energy with and without the n,p track component, and percent n,p tracks. From this the listed dose information is obtained.

The Kodak NTA response to the neutron irradiation at various depths in the phantom is presented in Fig. 14, which also contains for comparison the relative Ilford emulsion response.

Average energy and absorbed dose of proton recoils in the emulsions at various depths in the phantom were found as follows. To obtain the average energy of the proton recoils (Fig. 15) we calculated $E \cdot \frac{\Delta N}{P \Delta E} \cdot \Delta E/\Sigma \frac{\Delta N}{P \Delta E} \cdot \Delta E$ for the Ilford films C-1 to C-5, and C-9. The energy absorbed in the emulsion from proton recoils at various phantom depths is the product of the measured absolute track density and the average energy per track.
IV. DISCUSSION

The estimate of biological damage from ionizing radiation is usually based on the knowledge of the amount of energy imparted to the tissue and by what means, and on the energy distribution of the particles involved. The major part of the dose delivered by fast neutrons to tissue arises from hydrogen nuclei recoiling from elastic collision with the neutrons. In order to understand the biological effects of neutrons in humans it is necessary to know the detailed proton-recoil energy distribution at various depths within the body. Therefore, a suitable tissue neutron dosimeter is one that does not influence the local neutron distribution. Further, it must record exactly the recoil events in space, and it must be of small size. It is also desirable that the dosimeter be continuously sensitive, that it have a low gamma sensitivity, that many simultaneous measurements can be made, that the time between exposure and analysis be convenient, and that a permanent record be made. It is clear that nuclear track emulsion is superior to other dosimeters in these respects.

Used as described in this paper, nuclear emulsion is an absolute fast-neutron dosimeter which also yields the local differential proton tissue dose. Neutron-dose information can also be obtained by measurements with various metal foils, scintillators, and gas-filled proportional counters. The major advantage of all these detectors is the rapid availability of their information during or immediately following the irradiation, whereas 600-μ emulsion requires several days for development and scanning before yielding the dose information. The major disadvantages of scintillators and proportional counters are their size, and their dependence on attached electronic apparatus. The latter makes them considerably less versatile than foils and emulsion; and their size without question alters the local fast-neutron distribution and
makes it difficult to take measurements inside a human-sized phantom. Metal foils are basically neutron flux meters, and obtaining precise dose information from foils is difficult, even when they have been calibrated by the very neutron source whose tissue dose is being measured.

Table 3 gives the basic data concerning the effect of the presence of track emulsion on the local neutron distribution in tissue. The table reveals that for fast neutrons the total macroscopic cross sections of tissue and emulsion are nearly the same. Therefore the presence of emulsion is not expected to perturb the local fast-neutron spectra at various depths in tissue.

When fast neutrons impinge on the human body, large numbers of thermal neutrons are produced as the fast neutrons lose energy through multiple collisions. This is why the effect of a dosimeter on the local thermal-neutron density must also be considered. The ratio of the macroscopic absorption cross section for thermal neutrons in emulsion and in tissue is about 30/1. However, this does not appear to be important when the mean-square diffusion distance (as the crow flies) of thermal neutrons is compared to the emulsion thickness. This "distance" is about 16 cm$^2$ in tissue and 1 cm$^2$ in emulsion; the emulsion thickness is 0.060 cm. This means that the average net distance that a neutron travels from the time when it is produced until the time when it is captured is about 1 cm in emulsion and 4 cm in tissue. Therefore the thermal neutron density in the emulsion is not expected to differ from that in nearby tissue.

1. Interpretation of the track density distributions

The major feature of these track spectra, as revealed in Figs. 8 - 12, is that from about 0.8 to 2.5 MeV the track density decreases exponentially,
being proportional to $e^{-0.7E}$. Beyond 3 MeV, it is proportional to $e^{-0.9E}$.

This track-density distribution is what one theoretically expects for a PuBe neutron exposure of emulsion in air*. Proton recoil tracks from the thermal $N^{14}(n, p)C^{14}$ reaction, and from secondary neutron collisions with hydrogen nuclei, are superimposed on the basic distribution. The $n, p$ tracks are monoenergetic at 0.60 MeV and are quite prominent in the track spectra of emulsions C-2, C-3, and C-4. The secondary-collision tracks are largely below 1.5 MeV and are evident in the track spectra C-1 to C-4. The track density spectrum of C-5 shows the basic pattern with a relatively small thermal-neutron $N^{14}(n, p)C^{14}$ peak and only a slight secondary-neutron collision shift. The finding that the same distribution obtains at various depths indicates that the major features of the neutron spectrum are present even deep in the phantom.

Below 0.5 MeV, the efficiency of nuclear emulsion drops rapidly, giving the erroneous picture that the number of tracks falls. The track densities are expected to be about the same from 0.5 to 0 MeV as they are at 0.5 MeV. The curves have been corrected for this and for sampling bias, as discussed in the previous section.

2. Separation of the thermal $N^{14}(n, p)C^{14}$ track component, and estimation of the thermal neutron intensities

For determining proton-recoil emulsion dose there is no need to separate the component due to $n, p$ tracks, but it is important that this be done for calculating tissue dose.

*The expected track-density distribution was calculated from unpublished data on the PuBe neutron spectrum obtained by Lehman.
The thermal n,p track contribution was estimated by subtracting the percent of the tracks in the 0.54- to -0.66-MeV interval of the C-9 distribution (in which we assume there are no n,p tracks) from the percent in the same region in emulsions C-1 through C-5:

\[
\text{percent of thermal-neutron } n,p \text{ tracks} = A_i - (1 - A_i) k. \tag{1}
\]

where \( A_i \) is the percent of tracks in the 0.54- to 0.66-MeV region for the emulsion under consideration and \( k \) is \( A/(1 - A) \) for emulsion C-9. Table 4 gives the result.

3. Interpretation of total L.A track density and total NTA response vs depth in phantom

The major feature of the plots in Fig. 14 is the exponential attenuation of neutrons with depth, with an attenuation half thickness of 7.0 cm. This attenuation is for all fast neutrons present in the phantom that are detectable by nuclear track emulsion. Superimposed on this basic response is the response due to thermal-neutron \( ^{14}\text{N} \,(n,p)^{14}\text{C} \) tracks. It is this thermal-neutron response that distorts the basic 7.0 cm attenuation in the L.A plot, causing the extended hump in the center of the curve. The following brief explanation is an attempt to clarify this.

The NTA response to neutron exposure, in tracks/field, may be represented by the equation

\[
\text{NTA response} = a_n^{\text{th}} + b_n^f. \tag{2}
\]

Similarly, the L.A response, in tracks/cm\(^3\), may be represented by

\[
\text{L.A response} = c_n^{\text{th}} + d_n^f. \tag{3}
\]

In these equations, the coefficients \( a \) and \( b \) have the dimensions of tracks/field per unit thermal neutron \( n^{\text{th}} \) or fast neutron \( n^f \) per cm\(^2\).
The thermal n, p track contribution was estimated by subtracting the percent of the tracks in the 0.54- to -.66-Mev interval of the C-9 distribution (in which we assume there are no n, p tracks) from the percent in the same region in emulsions C-1 through C-5:

percent of thermal-neutron n, p tracks =

\[ A_i - (1-A_i)k, \] (1)

where \( A_i \) is the percent of tracks in the 0.54- to -0.66-Mev region for the emulsion under consideration and \( k \) is \( A/(1-A) \) for emulsion C-9. Table 4 gives the result.

3. Interpretation of total L. 4 track density and total NTA response vs depth in phantom

The major feature of the plots in Fig. 14 is the exponential attenuation of neutrons with depth, with an attenuation half thickness of 7.0 cm. This attenuation is for all fast neutrons present in the phantom that are detectable by nuclear track emulsion. Superimposed on this basic response is the response due to thermal-neutron \( ^{14}(n, p)C^{14} \) tracks. It is this thermal-neutron response that distorts the basic 7.0 cm attenuation in the L. 4 plot, causing the extended hump in the center of the curve. The following brief explanation is an attempt to clarify this.

The NTA response to neutron exposure, in tracks/field, may be represented by the equation

\[ \text{NTA response} = a_n^{\text{th}} + b_n^{\text{f}}, \] (2)

Similarly, the L. 4 response, in tracks/cm \(^3\), may be represented by

\[ \text{L. 4 response} = c_n^{\text{th}} + d_n^{\text{f}}. \] (3)

In these equations, the coefficients \( a \) and \( b \) have the dimensions of tracks/field per unit thermal neutron \( (n^{\text{th}}) \) or fast neutron \( (n^{\text{f}}) \) per cm \(^2\).
The coefficients \( c \) and \( d \) have the dimensions tracks/cm\(^3\) per unit thermal- or fast-neutron exposure. The difference in shape between the curves in Fig. 14 arises because \( c/d \approx 3 a/b \) for PuBe neutrons, that is, the relative response of L.4 to thermal neutrons, is roughly three times that of NTA. The reason that these ratios differ is that the NTA response includes tracks which originate in adjacent hydrogenous radiator material, \(^3\) whereas the L.4 response does not. (Only tracks that begin and end within the L.4 emulsion are scanned.)

4. **Calculation of tissue dose vs depth in the phantom**

To obtain the tissue thermal-neutron \( n, p \) track dose, the L.4 dose is multiplied by 0.406, the ratio of the nitrogen atomic density in tissue to that in L.4 emulsion. The result is plotted in Fig. 17 where the \( n, p \) tissue dose calculated here is shown to agree with the relative thermal neutron density measured by indium foil activation. To obtain the fast neutron proton track dose, the L.4 dose is multiplied by 1.86, the ratio of the atomic density of hydrogen in tissue to that in L.4 emulsion.

Fig. 16 gives the absolute differential proton tissue dose in tissue-equivalent liquid at various depths in the phantom. These curves were obtained from the basic track data in Table 1 by computing the points \( \frac{E \cdot \Delta N}{P \Delta E} \). Then the area under the \( n, p \) track peak at 0.60 MeV was reduced by 4.6, the factor giving the relative \( n, p \) response in emulsion as compared with tissue, and the points below 0.66 MeV were corrected as described earlier. The plotted curves are the smooth lines through the calculated points \( \frac{E \cdot \Delta N}{P \Delta E} \). The curves are normalized so that the total area under each curve equals the total dose, obtained from the product of the track density in tissue by the average proton energy in tissue. The error (in %) at any given energy on
these curves is roughly that of the proton track spectra at the same energy given in Table 1.

The differential dose values listed in Table 5 were obtained by finding the fractional areas under the dose curves in Fig. 16. It should be stressed that the dose distributions obtained here are the averages for about 200 millirad total exposure. Shorter exposures give track-by-track quantum distributions which approximate those shown here only if the exposures are roughly as great as those used in this work.

5. **Comparison of phantom proton dose with a predicted dose**

In Handbook 63 the tissue proton dose is calculated by assuming exposure of an infinite 30-cm-thick tissue-equivalent slab to monoenergetic neutrons of various energies. Table 6 compares the data for 2.5- and 5.0-MeV neutrons with our phantom data for PuBe neutrons. Two things are evident — the first is that at all depths our values are roughly 2/3 the 5.0-MeV values in Handbook 63. The second is that the proton dose attenuation with depth shows a half-thickness value of 10 cm for the phantom exposed to PuBe neutrons, compared with 5.5 cm and 8.5 cm for the slab exposed to 2.5- and 5.0-MeV neutrons.

A large part of the discrepancy between our values and the values of Handbook 63 for the absolute magnitude of the proton dose lies in the fact that Handbook 63 uses a value of 2.50 MeV for the average first-collision energy transfer between a 5.0-MeV neutron and a hydrogen nucleus. We found that the average energy of the recoil tracks in the C-1 to C-5 spectra (excluding thermal n, p tracks) varied between 1.21 and 1.57 MeV at the different depths, compared with 1.60 MeV in emulsion C-9, which was exposed
in air. The values at the 0-cm, 5-cm, 10-cm, and 15-cm depths are much lower than 1.60 MeV; this is evidence for a significant track contribution from second-collision neutrons. The average proton track energy at the back surface of the phantom (C-5) is 0.57 MeV — a surprisingly low value, since very few tracks here arise from secondary-neutron collision. This reveals that although there may be some hardening of primary neutron spectrum, many low-energy neutrons are present.

V. SUMMARY

Nuclear track emulsion was evaluated as a neutron dosimeter in the exposure of a human phantom to neutrons from a plutonium-beryllium source. Emulsion pieces were located at various positions in and around the phantom. The following basic information referring to each location was obtained by scanning 2-cm squares of 600-μ Ilford L.4 emulsion with a semiautomatic three-axis digitized microscope:

1. The absolute differential proton-recoil energy spectrum.
2. The average track energy.

From these data, the following dose information may be calculated:

1. The absolute differential local absorbed dose from proton tracks in tissue.
2. The local thermal neutron \( N^{14}(n, p)C^{14} \) dose in tissue.
3. The thermal neutron density and fast neutron flux in tissue.

In addition, the proton recoil spectrum reveals general information about the local fast-neutron energy spectrum.

In this experiment the total proton dose to tissue in the phantom varied from \( 3.1 \times 10^{-9} \) rad at the front surface to a low of \( 0.63 \times 10^{-9} \) rad at the
back surface per unit exposure to PuBe neutrons. Although large numbers of \( N^{14}(n, p)C^{14} \) tracks were observed inside the phantom, their contribution to the total dose in no case exceeded 2%.

**Acknowledgments**

The authors wish to thank Mr. James C. Hodges for the design, construction, and maintenance of the three-axis digitized microscope; Mr. Arthur W. Barnes for the design of the microscope electronics; Mr. John R. Meneghetti for making the phantom; Mr. John H. Wood and Miss Betty J. Lofstrand for processing the L.4 emulsions; Miss Olga M. Fekula for scanning the L.4 emulsions; Miss Dorothy A. Hadley and Miss Josephine A. Camp for scanning the NTA film; Mr. Carl Quong for preparing the computer program; and Mr. H. Wade Patterson and Dr. Roger W. Wallace for their continuous support.

The Probability that a Track of Given Length that Originates in the Emulsion Will Also End in the Emulsion

Two cases are considered; face-normal exposure and isotropic exposure. In both cases it is convenient to first consider the situation when the track length \( l \) exceeds the emulsion thickness \( T \), as in Fig. 18. Assume the emulsion has infinite lateral extent, and that the probability of a neutron-proton collision does not vary within the emulsion. Consider a track of length \( l \) originating at an arbitrary depth \( T - x \) in the emulsion. There is cylindrical symmetry about a line normal to the emulsion surfaces through the track origin.

**Case 1. Face-Normal Exposure**

Only tracks of this length that enter the solid angle about conical angle \( \phi \) end in the emulsion. In this case, the probability that a track will enter any solid angle is not constant, but is given by

\[
\frac{dn}{d\Omega} = \frac{N_0}{2\pi} \frac{\Omega}{\pi},
\]

where \( \Omega = 2\pi \sin \phi \). Therefore

\[
dP = \frac{dn}{N_0} = \frac{d\Omega}{2\pi} \left( \frac{\Omega}{\pi} \right)
\]

(2)

(where the quantity in parenthesis may be considered a weighting function);

\[
P(x) = \frac{2\pi x}{l} \frac{\Omega}{2\pi^2} d\Omega = \frac{x^2}{l^2} ;
\]

(3)

and

\[
P = \frac{3T^2}{3l^2}.
\]

(4)

To obtain \( P \) for \( l < T \), one divides the thickness of the emulsion into two pieces, \( l \) and \( T - l \).
For the fraction \( \frac{\ell}{T} \) the probability is \( \frac{1}{3} \), as given by Eq. (4), where 
\( \ell = "T" \). For the fraction \( \frac{T-\ell}{T} \) the probability is unity. Therefore 
\[
P (\ell < T) = \frac{\ell}{3T} + \frac{T-\ell}{T} = 1 - \frac{2\ell}{3T}.
\] (5)

Case 2. Isotropic Exposure

Only tracks of this length that enter the solid angle of cone \( \phi \) end in the emulsion. In this case, 
\[
\frac{dn}{d\Omega} = \frac{N_0}{4\pi} = \text{constant},
\] (6)
and 
\[
\frac{dP}{N_0} = \frac{dn}{4\pi} \quad \text{(1)}
\] (7) 
(the quantity in parenthesis is a weighting function, corresponding to that in Case 1), 
\[
P = \int_0^{2\pi} \frac{d\Omega}{4\pi} \int_0^{2\pi} \frac{d\Omega}{4\pi} \frac{T-x}{\ell},
\] (8)
where 
\[
\frac{x}{\ell} = \cos (\phi - \theta) \quad \text{and} \quad \frac{(T-x)}{\ell} = \cos \theta,
\] (9) 

\[
P = \frac{x}{2\ell} + \frac{T-x}{2\ell} = \frac{T}{2\ell} \quad \text{independent of} \ x.
\] (10)

As in Case 1, to obtain \( P (\ell < T) \), the probability for the fraction \( \frac{\ell}{T} \) is \( \frac{1}{2} \), and that for the fraction \( \frac{T-\ell}{T} \) is unity. Therefore 
\[
P (\ell < T) = \frac{\ell}{2T} + \frac{T-\ell}{T} = 1 - \frac{\ell}{2T}.
\] (11)

EMULSION HISTORY CHART

Emulsion # C-1
Type 1,4 JHard 600μ
Batch code 2-2581

Date Manufactured 8-9-61

Date of arrival at UCLRL 8-23-61

Storage: Location 7 House
Dates 8-23-61 to 8-29-61

Location Bldg 72 RM 103
Dates 8-29-61 to 9-1-61

Location Bldg 47 Tech Photo
Dates 9-5-61 1:00 to 9-7-61 date due!

Exposure: Location Bldg 80A
Type of exposure BaBe neutron source 1955
Duration 9-1-61 to 9:00 9-5-61
Distance from source 39.4 cm
Orientation Normal to axis of incident neutrons. Outside front cover of
phantom containing "tissue equivalent" liquid.

Scattering conditions schematic drawing

Diagram See Notebook

Development: Procedure Modified cold cycle + 24 hr soak in ethylalcohol/5%

Personnel B. Holtsrand and J. Wood

Location Bldg 47 Tech Photo
Dates 9-7-61 to 9-14-61

Comments Well developed throughout.

Mounting: 1 X 3 glass slide
Epoxy cement

Date 9-18-61 Person RLL

Comments Mounted with C-2 and C-3

Scanning: Scanner O.M. Fekula

No. of tracks 438

Date 9-27-61

Scanner No. of tracks

Date to

Location of data cards

Emulsion code no. 301 1.0 0.5 0.66

Comments Easy to scan 5.4 x 10^6/cm^2 (avg. of 10 fields in depth)

Analysis: Program RECON T

Tracks used 438

Date 9-27-61 Person RLL

Program RECON 2P

Tracks used 438

Date 1-33-62 Person RLL

Date Person

Comments No steps - a good computer run 1-23-62

Shrinkage: Thickness before presoak - micrometer (inches)

Date 9-5-61 RH 50% 0.0256 0.0255 0.0253 0.0262 0.0266 Av 0.0258 in.

Thickness after development - before mounting - micrometer

Date 9-13-61 RH 69% 0.0233 0.0240 0.0232 0.0236 0.0237 Av 0.0235 in.

Thickness after mounting - microscope

Date RH Average μ x .393 = 0.0 in.

Lateral Distortion: Dimensions before presoak - 64th inch scale

Date 9-5-61 50/64 51/64 64/64 69/64 Av 57.2 64

Dimensions after development - before mounting

Date 9-13-61 53/64 53/64 66/64 66/64 Av 57 /64

Dimensions after mounting

Date

Subsequent Measurements: S = 57.2 /9 = 0.97 8 = 0.600 x 0.005 = 0.006

Note that the resin soak treatment reduces the vertical (z) shrinkage
to 11.9% in this case.
