NEUTRON-PROTON SCATTERING AT 300 MEV

J. De Pangher

Radiation Laboratory, Department of Physics
University of California, Berkeley, California
May 10, 1954

A Wilson cloud chamber, containing only hydrogen and water vapor, was photographed stereoscopically in a magnetic field of strength 22,000 gauss to obtain data on the protons scattered by 300-Mev neutrons. Certain selection criteria were adopted for the measurements of the tracks, which were obtained in two runs at the Berkeley cyclotron. A lower limit of 155 Mev was set on the neutron energy for a track to be accepted. Definite regions of the cloud chamber were chosen for the measurements in each of the two runs. Tracks whose dip angles exceeded 50° were excluded from measurement. The scatter angle was generally limited to 85°, although a few tracks were measured with angles up to 86° to make sure no 85° tracks were missed.

The energy spectrum for the neutrons that were produced in a LiD target, 1-3/4 in. thick, by 340-Mev protons inside the cyclotron is shown in Fig. 1. This spectrum was derived from the original histogram of the cloud-chamber data by an error-unfolding process. A total of 1425 tracks were selected from the angular group (scatter angles less than 85° and dip angles less than 75°) for which the energy measurements are best. The omission of tracks with dip angles exceeding 25° is accounted for by applying an azimuthal correction factor, based on the assumption of azimuthal symmetry. The effect of the variation of the total n-p scattering cross section with the neutron energy was included in the error-unfolding process.

In order to justify the assumption of uniform distribution of the protons in the azimuthal angle (measured in a plane perpendicular to the direction of the neutron beam) tabulations of the data were made. Figure 2 shows the azimuthal distribution for dip angles less than 40° and for

neutron energies above 200 Mev. Tracks with dip angles greater than 40° fall into the excluded region and are not tabulated. The number of tracks for any square or partial square is given inside the square. The numbers within any vertical column and contained in whole squares should agree within the limitations imposed by the statistical errors of measurement. A consideration of these data shows that the assumption of uniformity of the azimuthal distribution is valid.

Table I lists the angular distribution data, based on 2057 tracks, for the neutrons in the center-of-mass system. The data are limited to neutrons with energies above 200 Mev and to protons with dip angles less than 40°. The geometrical correction factor has the value unity for proton deflection angles less than 40°, but above 40° the value of this factor rises steadily up to the value 2.25 at 90°. By assuming a total n-p cross section of 35 mb, it is possible to calculate the differential cross section from the total weighted number of tracks. However, the standard statistical errors in the differential cross section are based on the uncorrected number of tracks in the 10-degree angular intervals. The upper limit on the standard error in the neutron angle in the center-of-mass system is estimated to be ± 3.0°, while the average standard error is estimated to be ± 1.5°.

The data contained in Table I are plotted in Fig. 3 in histogram form. They are to be compared with the data obtained with counters by Kelly, Leith, Segre, and Wiegand, who reported neutron energies (about 260 Mev) somewhat smaller than the neutron energies measured in the present experiment. The agreement is considered satisfactory. The special point was computed from a smooth curve drawn through the counter data to illustrate how the cloud chamber with its selected 10-degree channel width would depict this rapidly changing portion of the angular-distribution curve. The cloud-chamber data extended into smaller neutron angles than do the counter data and clearly show a marked departure from symmetry about 90° in contrast to the 90-Mev data, which exhibit symmetry about 90°.

Thanks are due to Professor W. M. Powell, who suggested this problem, and whose encouragement and interest in the progress of the work have been a constant inspiration to this writer.
