CAPILLARY WAVEGUIDE FOR LASER ACCELERATION IN VACUUM, GASES, AND PLASMAS

MING XIE, Lawrence Berkeley National Laboratory, Berkeley, USA

Abstract

I propose a new method for laser acceleration of relativistic electrons using the leaky modes of a hollow dielectric waveguide. The hollow core of the waveguide can be either in vacuum or filled with uniform gases or plasmas. In case of vacuum and gases, TM01 mode is used for direct acceleration. In case of plasmas, EH11 mode is used to drive longitudinal plasma wave for acceleration. Structure damage by high power laser is avoided by choosing a core radius much larger than laser wavelength.

1 EIGENMODE PROPERTIES

The capillary waveguide considered here is made of a hollow core with an index of refraction \( n_1 \) and radius \( R \), embedded in a dielectric medium with an index of refraction \( n_2 \). We are interested in the regime with \( \lambda_1/R \ll 1 \), where \( \lambda_1 = \lambda/n_1 \) and \( \lambda \) is the wavelength in vacuum. As a result, the EM wave in the core is dominantly transverse. Assuming \( \sqrt{\gamma^2 - 1} \gg \lambda_1/R \), where \( \gamma = n_2/n_1 \), the eigenmodes of the waveguide can be solved following the same procedure by Marcotili and Schmeltzer [1].

Expressing the eigenmodes in the following form

\[
\begin{bmatrix}
E \\
H
\end{bmatrix} = \begin{bmatrix}
E_{lm}(r, \phi) \\
H_{lm}(r, \phi)
\end{bmatrix} e^{i(\beta_{lm} - \omega t) - \alpha_{lm} z},
\]

the eigenvalues are given by

\[
\beta_{lm} = \frac{2\pi}{\lambda_1} \left( 1 - \frac{1}{\sqrt{\gamma^2 - 1}} \right), \quad \alpha_{lm} = \chi/\gamma^2 R,
\]

where \( \gamma^2 = 2\pi R/\lambda_1 \gg 1 \), and \( \lambda_1 \) is the mth root of the equation, \( J_{l-1}(U_{lm}) = 0 \). There are three types of modes, corresponding to

\[
\chi = \begin{cases}
\frac{1}{\sqrt{\gamma^2 - 1}} : & TE_{0m} \quad (l = 0) \\
\frac{\sqrt{\gamma^2 - 1}}{\gamma^2 - 1} : & TM_{0m} \quad (l = 0) \\
\frac{\sqrt{\gamma^2 - 1}}{2\sqrt{\gamma^2 - 1}} : & EH_{lm} \quad (l \neq 0)
\end{cases}
\]

For laser acceleration, we are interested primarily in two modes: TM01 mode for acceleration in vacuum and in gases, and EH11 mode for acceleration in plasmas. Correspondingly, we consider three cases: \( \delta \nu_1 = 0 \) when the core is in vacuum, \( \delta \nu_1 > 0 \) and \( \delta \nu_1 < 0 \) when the core is filled with gases and plasmas, respectively, where \( \delta \nu_1 = \nu_1 - 1 \) and \( |\delta \nu_1| \ll 1 \). It is noted that EH11 mode is often designated as HE11 mode elsewhere in literature, in this paper we follow the notation in reference [1].

The TM01 mode is given to the leading order by

\[
(r \leq R) : \begin{cases}
E_z = E_0 J_0(k_{r1} r) \\
E_r = -i\gamma E_0 J_1(k_{r1} r) \\
H_r = E_r/Z_0,
\end{cases}
\]

Similarly, EH11 mode is obtained as

\[
(r \leq R) : \begin{cases}
E_z = E_0 J_0(k_{r2} r) \\
E_r = -i\gamma E_0 J_1(k_{r2} r) \\
H_r = E_r/Z_0,
\end{cases}
\]

where \( E_0 \) is the peak acceleration field, \( E_0 \) the peak transverse field, \( Z_0 \) the vacuum impedance, and \( k_{r1} = (U_{lm} - i\chi/\gamma_0)/R \). The only dominant transverse components are specified for EH11 mode. For \( r \geq R \), all fields have the radial dependence \( \exp(ik_{r2} r)/\sqrt{r} \), where to leading order \( k_{r2} = k_1\sqrt{\nu^2 - 1} \). A non-vanishing imaginary part of \( \nu \) due to slightly lossy dielectric medium will give rise to exponential decay of fields in radial direction.

Notice EH11 mode is linearly polarized, while TM01 mode is radially polarized. However, when necessary, linearly polarized mode can be formed by a proper mixing of TM01 with another hybrid mode, EH31 mode, while preserving \( E_0 \) of TM01 mode on the axis. For the three modes we have \( U_{11} = 2.405 \), and \( U_{01} = U_{21} = 3.832 \).

An important concern for using a waveguide for laser acceleration is power damage on the structure. To evaluate surface field, we expand the dominant transverse field at \( r = R \) using the expression for \( k_{r1} \) and obtain

\[
\frac{E_s}{E_0} = \frac{x}{\gamma_0} |J_0(U_{01})| : TM_{01},
\]

\[
\frac{E_s}{E_0} = \frac{x}{\gamma_0} |J_1(U_{11})| : EH_{11}.
\]

For TM01 mode, surface field is of the same order as the peak acceleration field. For both modes surface fields are much smaller than the peak transverse field.

Coupling between the waveguide modes to free space Gaussian-Laguerre modes is very efficient. When focused at the waveguide input cross section, power coupling from TM01 to TM01 reaches a maximum of 97% at \( w_0/R = 0.56 \), and from TEM00 to EH11 is 98% at \( w_0/R = 0.64 \), where \( w_0 \) is the Gaussian beam waist. Despite the fact that the modes are leaky the guiding can be quite effective with rather long \( 1/e \) power attenuation length \( \lambda_{attm} = \gamma_0^2 R/2x \).

2 ACCELERATION IN VACUUM

According to Eq.(2), phase velocity of the TM01 mode is larger than the speed of light, \( c \)

\[
v_p = \frac{\omega}{\beta_{01}} = \frac{c}{1 - \frac{1}{2\gamma^2}}.
\]

We define an acceleration phase slippage length over which a relativistic electron, while gaining energy, slips a full \( \pi \) phase with respect to the acceleration wave

\[
L_a = \frac{\lambda}{1/\gamma_0^2 + 1/\gamma^2}.
\]
Over this distance, energy gain of the electron on-axis is

$$\Delta W_a = eE_a \int_0^{L_a} \sin(\pi z/L_a) dz = eE_a L_a T_a, \quad (10)$$

where $T_a = 2/\pi$ is a reduction factor due to a $\pi$ phase slippage during acceleration. Here we have neglected the small attenuation of the acceleration field over a distance $L_a$. In parallel, let’s also define a deceleration length, $L_d$, over which the electron slips another $\pi$ phase while losing energy $\Delta W_d = eE_a L_d T_d$, where $T_d$ can be different from $T_a$ if $L_d/L_a \neq 1$. The average acceleration gradient during a period of $2\pi$ phase slippage is then given by

$$G = \frac{\Delta W_a - \Delta W_d}{L_a + L_d} = G_a \frac{1 - (L_a/L_d)(T_d/T_a)}{1 + L_d/L_a}, \quad (11)$$

where $G_a = \Delta W_a/L_a = eE_a T_a$. To have net acceleration, the ratio $L_a/L_d$ should be made small. This can be done by introducing a magnetic field during the half period of deceleration. The effect of magnetic field is to reduce longitudinal velocity of the electron such that it slips faster, thus taking less time or shorter distance, $L_d$.

For simplicity, we assume the field is sinusoidal with a period $\lambda_w$, $B_y = B_0 \cos(2\pi z/\lambda_w)$. The length $L_d$ for a $\pi$ phase slippage is then defined by

$$\left[ \frac{1}{\gamma^2} + \frac{1}{\gamma_2^2} \right] \pi L_d = \frac{a^2_w \lambda_w}{\gamma^2} \sin \left[ \frac{4\pi L_d}{\lambda_w} \right] \pi, \quad (12)$$

where $a_w = eB_0 \lambda_w/2\pi\sqrt{2mc}$. If we set $\lambda_w = L_d$ then

$$L_d = \frac{\lambda}{1/\gamma_2^2 + 1/\gamma^2 + a^2_w/\gamma^2}, \quad (13)$$

and $a_w$ is now determined by

$$a_w = \sqrt{Q_1 + \sqrt{Q_1^2 + Q_2^2} + \sqrt{Q_1 - \sqrt{Q_1^2 + Q_2^2}}, \quad (14)$$

with $Q_1 = eB_0 \lambda^2/4\pi\sqrt{2mc}$ and $Q_2 = [1 + (\gamma/\gamma_2)^2]/3$. Due to longitudinal oscillation, $T_d$ is different from $T_a$

$$T_d = \frac{1}{\pi} \int_0^\pi \sin [\theta - \kappa \sin (4\theta)] d\theta, \quad (15)$$

where $\kappa = (1 - L_d/L_a)/4$. The value of $T_d$ varies in the range $\{1.84 \rightarrow 2\}/\pi$ for $L_d/L_a$ in the range $\{0 \rightarrow 1\}$. We have assumed the electron is decelerated by the on-axis value of $E_x$, but as the electron is deflected off-axis, it will see a weaker field. The maximum transverse orbital offset in the wiggler field is $\Delta X_{max} = \sqrt{2a_w \lambda_w/\pi \gamma}$.

Due to magnetic deflection, electron will radiate and lose energy. Energy loss per wiggler period is

$$\Delta W_s = \frac{8\pi^2 mc^2}{3} \left( \frac{r_e}{\lambda_w} \right) a^2_w \gamma^2, \quad (16)$$

where $r_e$ is the classical radius of electron. The maximum possible energy that can be accelerated with this method can be determined by the condition: $\Delta W_a > \Delta W_d + \Delta W_s$.

Transverse forces due to EM wave do not cancel to order of $1/\gamma^2$ in a waveguide mode, thus giving rise to either focusing or defocusing depending on acceleration phase, $\phi_a$, which varies constantly due to slippage. The corresponding beta function is

$$\beta_a = \gamma a \sqrt{(\gamma mc^2/\pi eE_a \sin \phi_a)/(1 - (\gamma_a/\gamma)^2)}, \quad (17)$$

the term grouped in the first bracket on the right is the ratio of electron energy to its energy gain per wavelength.

### 3 ACCELERATION IN GASES

The phase velocity of the $TM_{01}$ mode in gases is given by

$$v_p = \frac{\omega}{\beta_{01}} = \frac{c}{1 - 1/2\gamma^2 + \delta \nu_1}. \quad (18)$$

The corresponding phase slippage length is then

$$L_{slip} = \lambda \sin \left( \frac{1}{1/\gamma^2 + 1/\gamma^2 - 2\delta \nu_1} \right). \quad (19)$$

The phase matching condition is obtained by making the denominator zero, thus $\delta \nu_1 = 1/2\gamma^2 + 1/2\gamma^2$. This condition suggests an alternative way to maintain phase matching as $\gamma$ increases during acceleration: instead of varying $\delta \nu_1$, one may change $\gamma_a$ by tapering waveguide radius. The beta function in gases is smaller than that in vacuum by a factor of $\sqrt{2}$ in the limit $\gamma_a/\gamma \ll 1$.

### 4 ACCELERATION IN PLASMAS

Wave equation for laser field propagation in weakly relativistic plasmas under cold fluid condition is given by

$$\left[ \nabla^2 - \frac{1}{c^2} \frac{\partial^2}{\partial t^2} \right] E_t = \frac{\omega^2_p}{c^2} \left[ 1 + \frac{\delta n}{n_0} - \frac{a^2}{2} \right] E_t. \quad (20)$$

The plasma density modulation, $\delta n/n_0$, driven by the ponderomotive potential of a laser pulse, $a^2 = <|eE_t/\omega c\lambda|^2>$, will generate a wakefield, $E_w = -\nabla \Phi$, where the wake potential, $\Phi$, is determined by

$$\left[ \frac{\partial^2}{\partial t^2} + \omega_p^2 \right] \Phi = \omega_p^2 \frac{mc^2 a^2}{e}. \quad (21)$$

To close the loop, $\delta n/n_0$ is given by Poisson's equation:

$$\nabla^2 \Phi = (e/e_0) \delta n/n_0, \quad \text{where} \quad \omega_p = \sqrt{e^2 n_0/\epsilon_0 m} \quad \text{and} \quad \epsilon_0 = 1/Z_0. \quad \text{The approach here parallels to that in reference [2].}$$

Under the condition $a^2 \ll 1$, we will have $\delta n/n_0 \ll 1$. As a result, the second and third term on the right of Eq.(20) can be dropped and the wave equation is then decoupled from the plasma equations. The only effect of plasma on laser propagation is through an index of refraction $\nu_1 = 1 - \omega_p^2/2\omega^2$. Consider a capillary tube filled with a uniform plasma of density $n_0$, a laser pulse propagating through the waveguide will excite a wakefield with phase velocity
equals the group velocity of the pulse. For $EH_{11}$ mode, the group velocity is given by

$$v_g = \frac{d\omega}{d\beta_{11}} = \frac{c}{1 + 1/2\gamma_0^2 + 1/2\gamma_0^2},$$

(22)

where $\gamma_p = \omega/\omega_p \gg 1$. Introducing a variable $\zeta = z - v_gt$, Eq.(21) can be solved as

$$\Phi = -\left( k_p mc^2/e \right) \int_0^\infty d\zeta' \sin [k_p (\zeta - \zeta')] \frac{\alpha^2}{\zeta^2},$$

(23)

where $k_p = \omega_p/v_g$. For a Gaussian pulse of $EH_{11}$ mode

$$a^2(\rho, \zeta) = \frac{a^2}{2} J_0^2(U_{11}\rho) e^{-\zeta^2/2\sigma^2} - z/L_{attn},$$

(24)

where $\rho = r/R$, the wake potential behind the pulse is

$$\Phi = -\Phi_0 J_0^2(U_{11}\rho) e^{-z/L_{attn}} \sin (k_p z - \omega_p t),$$

(25)

$$\Phi_0 = \left( 2\pi mc^2/4e \right) a^2 k_p \sigma_z e^{-(k_p \sigma_z)^2/2}.$$ 

(26)

Longitudinal wakefield is then given by

$$E_{wz} = E_a J_0^2(U_{11}\rho) e^{-z/L_{attn}} \cos (k_p z - \omega_p t),$$

(27)

and transverse wakefield by

$$E_{wr} = -2(\gamma_p/\gamma_g) E_a J_0(U_{11}\rho) J_1(U_{11}\rho) e^{-z/L_{attn}} \sin (k_p z - \omega_p t),$$

(28)

where the peak acceleration field, $E_a = \Phi_0 k_p$, is maximized if the laser pulse length is chosen according to the condition $k_p \sigma_z = 1$. From here on, we will use this optimal condition wherever it is relevant.

There are several characteristic length parameters for laser wakefield acceleration. First, the slippage length is

$$L_{slip} = \frac{\lambda_p}{[1/\gamma_0^2 + 1/\gamma_0^2 - 1/\gamma^2]},$$

(29)

Next, the pump depletion length, $L_{pump}$, is defined by the condition $W_i = W_w$, where $W_i$ is the initial energy of the laser pulse given by

$$W_i = \frac{\sqrt{2\pi} J_1^2(U_{11}) R^2 \lambda_p E_0^2}{4Z_0 c},$$

(30)

and $W_w$ is the energy in the wakefield laser pulse left behind as it propagates a distance $L_{pump}$, given by

$$W_w = \left( \pi mc^2/4e \right) [\sin(1)/\exp(1)] a^2 \sigma_z^2 R^2 L_{pump}[I_z + (\gamma_p/\gamma_g)^2 I_r].$$

(31)

The two terms above correspond to energy in the longitudinal and transverse wakefield, respectively, and the defined integrals have the value $I_z = \int_0^1 dp \rho J_0^2(U_{11}\rho) = 0.0762$, $I_r = \frac{1}{2} \int_0^1 dp \rho J_0^2(U_{11}\rho) J_1^2(U_{11}\rho) = 0.00635$. We then have

$$L_{pump} = \frac{[4\sqrt{2\pi} J_1^2(U_{11}) \exp(1)/\pi^2]}{\lambda_p a^2 (I_z/\gamma_0^2 + I_r/\gamma_0^2)},$$

(32)

In calculating $W_w$ we have left out the attenuation factor $\exp(-z/L_{attn})$ since it is characterized by a separate quantity, $L_{attn}$. Given group velocity dispersion, Eq.(22), a pulse will double its length over a propagation distance

$$L_{disp} = \frac{\sqrt{3} \gamma_0^2}{\pi(1/\gamma_0^2 + 1/\gamma_0^2)}. \quad (33)$$

Finally, the beta function due to the transverse wakefield is

$$\beta_t = (2/\gamma_1)[\exp(1)/2\pi]^{1/2} \sqrt{\gamma - R \sin \phi_a \phi_b}.$$

(34)

5 EXAMPLES

In the following examples we will use $\lambda = 1\mu m$, $\nu_2 = 1.5$, assume an initial electron energy of 1 GeV, set $\sin \phi_a = 1$, and neglect the small difference between $T_a$ and $T_d$.
