Abstract

Traffic congestion and traffic flow instabilities in general in urban freeways are often caused by adhoc velocities and headways that humans choose when they operate their vehicles. In an automated highway system (AHS) environment, the driver actions are replaced by those of a computer control system that is designed to optimize traffic flow. On the microscopic level, each vehicle is driven by a computer control system that based on the actions of the surrounding vehicles, sends the appropriate commands to the throttle/brake/steering actuators. On the macroscopic level, a roadway controller calculates the desired speed commands to be followed by vehicles in each section of the freeway lanes in order to achieve desired traffic density distributions that lead to optimum traffic flow conditions.

The purpose of this paper is to design, analyze and simulate a roadway controller for a single automated highway lane that achieves desired traffic densities along the lane. A macroscopic traffic flow model that is modified for AHS operation is used for control design and analysis. We have shown that the proposed roadway controller guarantees exponential convergence of the traffic density at each section of the lane to the desired density. Simulation results are used to illustrate the effectiveness of the
proposed controller and the significant benefits AHS may bring to traffic flow.

**Keywords**  macroscopic traffic flow models, roadway controller, traffic density controller, automated highway systems
Executive Summary

In this paper a roadway controller is designed, analyzed and simulated for a single automated highway lane. All the vehicles in the lane are assumed to be equipped with microscopic throttle/brake controllers that enable automatic vehicle following. The roadway controller sends the appropriate speed commands to vehicles at each section of the highway so that the vehicle density along the lane converges to a desired one. The vehicle respond to the roadway speed commands without any driver interference. The design and analysis of the roadway controller is based on a macroscopic traffic flow model. The controller is developed using a backstepping approach, a tool that is often used for nonlinear control design. The traffic flow model and controller are simulated for single lane that has initially a non-uniform traffic density distribution. The simulation results demonstrate the effectiveness of the proposed controller and the significant benefits vehicle/roadway automation may bring to traffic flow.

1 Introduction

Urban freeway congestion is a growing problem that is demanding the attention of transportation authorities around the world. Solutions to this problem are actively sought not only to ensure shorter and more reliable travel times, but also to diminish its adverse effects on pollution and wasted fuel consumption.

A rudimentary approach to the congestion problem involves proper on-ramp metering at freeway entrance ramps to regulate the flow of incoming traffic to a freeway (Greenlee et al. 1977, Papageorgiou 1983, Papageorgiou 1986, Papageorgiou et al. 1990, Payne et al. 1973, Yuan et al. 1968). Advisory message boards placed at various points along the freeway, advising freeway users about speed limits, traffic conditions and alternative routes have also been used as a means of controlling congestion. Current research on automated highway systems (AHS) which propose microscopic control through vehicle following or platooning (Greenlee et al. 1977, Papageorgiou 1983, Papageorgiou 1986, Papageorgiou et al. 1990, Payne et al. 1973, Yuan et al. 1968) or macroscopic control to homogenize traffic density (Rao et al. 1992, Chien et al. 1994) allow a more sophisticated solution to this problem. In this paper, we present the design and analysis of a roadway controller that operates on a macroscopic level to relieve freeway congestion and improve traffic flow. The goal of the macroscopic control approach is to prevent congestion or at least avoid its amplification caused by traffic inhomogeneities. This is addressed by seeking control strategies that help to achieve a homogeneous traffic density profile (Rao et al. 1992, Chien et al. 1994). However, due to the strong coupling and the nonlinear dynamics associated with the traffic flow model, no theoretical analysis of the efficacy of such controllers can be found in the literature. Rather, the validity of any such proposed control scheme is only justified through a simulation study or by experimental results on a particular freeway. The design of a theory supported macroscopic controller is an issue that is yet to be addressed.

In this paper we provide a solution that addresses the above concerns. More specifically, we propose a roadway traffic controller that operates on a macroscopic level to homogenize traffic density of a congested freeway. We support the analysis and design of our scheme using the theory of nonlinear integrator backstepping that has been developed recently. Simulations show that our proposed method drastically reduces congestion and helps to achieve a smooth traffic flow on a congested freeway.

This paper is organized as follows. In sections 2 and 3, a discrete traffic flow model is presented and the problem statement is given. In section 4, the details pertaining to the design and analysis of the proposed roadway controller are given. Simulation results which show the benefits of our scheme are presented in section 5. Conclusions and future research directions are given in section 6.
2 Traffic Flow Model

The analogy between traffic flow and fluid dynamics formed the basis for the first traffic flow model proposed by Lighthill and Whitham (Lighthill et al. 1955). Their model which had traffic density as its only state variable showed poor transient behavior. Payne (Payne 1971, Payne 1979), Cremer and May (Cremer et al. 1985) proposed several modifications to overcome this problem. A more sophisticated model was proposed by Papageorgiou in (Papageorgiou 1983, Papageorgiou 1989, Papageorgiou 1990) which has been tested and validated using real traffic data from the Boulevard Peripherique in Paris. However, Karaaslan, Varaiya and Walrand (Karaaslan et al. 1990) demonstrated several shortcomings of Papageorgiou’s model, and proposed a more realistic model. This model forms the basis of our control design and its description follows below.

Consider a single freeway lane which is subdivided into N sections with lengths $L_i, (i = 1, 2, \ldots, N)$ as shown in Figure 1.

![Figure 1: A freeway system subdivided into sections](image)

The space and time discretized traffic flow model for a segment of the lane involves the following variables:

- $k_i(n)$ := Density in section $i$ at time $nT$ (in veh/km/lane), where $n = 1, 2, \ldots$
- $v_i(n)$ := Space mean speed of vehicles in section $i$ at time $nT$ (in km/h).
- $q_i(n)$ := Traffic volume leaving section $i$, entering section $i + 1$ at time $nT$ (in veh/h).
- $r_i(n)$ := On-ramp traffic volume for section $i$ (in veh/h).
- $s_i(n)$ := Off-ramp traffic volume for section $i$ (in veh/h).
- $L_i$ := Length of the $i$-th section (in km).
- $T$ := Time discretization step size (in h).
- $veh$ := Number of vehicles.
- $h$ := Hours.
- $km$ := Kilometers.

The modified freeway traffic flow model given in (Karaaslan 1990) is in the following form:

$$q_i(n) = \alpha k_i(n) v_i(n) + (1 - \alpha) k_{i+1}(n) v_{i+1}(n)$$  \hspace{1cm} (1)

$$k_i(n + 1) = k_i(n) + \frac{T}{L_i} [q_{i-1}(n) - q_i(n) + r_i(n) - s_i(n)]$$  \hspace{1cm} (2)
\[ v_i(n+1) = v_i(n) + \frac{T}{\tau} \{ V_e[k_i(n)] - v_i(n) \} + \frac{T}{L_i} \frac{k_{i-1}(n)}{k_i(n) + \kappa} v_{i-1}(n) \sqrt{v_{i-1}(n)v_i(n)} - v_i(n) \] 
\[-\frac{\mu(n) T}{\tau L_i} w_i(n) \] (3)

where

\[ \mu(n) = \begin{cases} \frac{\mu_1 k_{jam} - k_{i+1}(n) + \sigma}{\mu_2} & \text{if } k_{i+1}(n) > k_i(n) \\ \mu_2 & \text{otherwise} \end{cases} \]

Here \( \alpha, \rho, \sigma, \kappa', \tau, \mu_1, \mu_2 \) are positive constants with \( 0 \leq \alpha \leq 1 \), and \( k_{jam} \) is the maximum possible density. The variable \( V_e[k_i(.)] \) in equation (3) represents the density dependent equilibrium speed. In a manual operating environment with homogeneous traffic conditions, this relationship has been characterized in (Papageorgiou 1989, Papageorgiou 90 et al.) as

\[ V_e(k_i) = v_f \left( 1 - \left( \frac{k_i}{k_{jam}} \right)^m \right) \] (4)

where \( 1 > 0 \) and \( m > 1 \) are real-valued parameters and \( v_f \) is the free speed that can be estimated from traffic data.

The term \( w_i(n) \) in equation (3) under manual operation depends on the downstream density and can be expressed as

\[ w_i(n) = \frac{k_{i+1}(n) - k_i(n)}{k(n) + \kappa} \] (5)

where the positive constant \( \kappa \) is introduced to prevent abnormal growth of the velocity for section \( i \) when its density is very low.

Typical parameter values associated with the above model are tabulated in table 1 below.

Table 1: Parameters associated with the traffic model
Boundary conditions

We assume that the traffic flow rate entering section 1 during the time period \( nT \) and \( (n + 1)T \) is \( q_0(n) \) and the mean speed of the traffic entering section 1 is equal to the mean speed of section 1, i.e., \( v_0(n) = v_1(n) \). In addition, we also assume that the mean speed and traffic density of the traffic exiting section \( N + 1 \) are equal to those of section \( N \), i.e., \( v_{N+1}(n) = v_N(n) \), \( k_{N+1}(n) = k_N(n) \). Hence, the boundary conditions for the entrance and exit can be summarized as follows.

\[
\begin{align*}
    b(n) & = \frac{q_0(n) - (1 - \alpha)k_1(n)}{\alpha} \quad (6) \\
v_0(n) & = v_1(n) \quad (7) \\
k_{N+1}(n) & = k_N(n) \quad (8) \\
v_{N+1}(n) & = v_N(n) \quad \forall n. \quad (9)
\end{align*}
\]

The physical meaning of each term of equation (3) which influences the mean speed of a section can be interpreted as follows (Papageorgiou 1983, Karaaslan et al. 1990).

The second term \( \frac{1}{\tau} \{ V_e[k_i(n)] - v_i(n) \} \) is the relaxation term which accounts for the evolution of the mean speed \( v_i(n) \) towards its density dependent equilibrium speed \( V_e[k_i(n)] \) with a time constant \( \tau \). The dependence of \( V_e[k_i(n)] \) on the density is influenced by the environment in which the traffic flow is operating. For manual operation, this relationship is governed by (4) as reported in (Papageorgiou et al. 1989, Papageorgiou et al. 1990). For a fully automated highway system (AHS) operating under homogeneous heavy traffic conditions, the adopted safety policy for vehicles defines this relationship. For instance, if the desired safety distance between two vehicles \( S_d \) is made to depend on the equilibrium velocity \( V_e \) as

\[ S_d = \varphi(V_e) \]

then the density-equilibrium speed relationship can be characterized by,

\[ V_e(k_i) = \varphi^{-1}\left( \frac{1}{k_i} \right) \quad (10) \]

where \( \varphi^{-1}(\cdot) \) is the inverse function of \( \varphi(\cdot) \), i.e., \( x = \varphi^{-1}(y) \) satisfies the equation \( \varphi(x) = y \).

If the constant time headway policy is adopted as the criteria for selecting headways for vehicles, then

\[ S_d = hV_e + c \]

where \( h \) and \( c \) are constants. From this it follows that

\[ V_e(k_i) = \frac{1}{h k_i} - \frac{c}{h} \]

The third term \( \frac{T}{\sum k_i(n) + \alpha} \sum v_{i-1}(n) [v_i(n) - v_i(n)] \) in equation (3) is the convection term. It represents the influence of the incoming traffic on the mean speed evolution in segment \( i \).
The last term $w_i(n)$ in equation (3) is the anticipation term. It reflects the effect of downstream traffic density on the mean speed evolution in section $i$ at sampling time $nT$. For instance, if the density downstream is lower, this term reflects the tendency of human drivers to increase vehicle speed.

For an automated highway system (AHS), the anticipation term is no longer under human control. It depends on the control law used by AHS to control traffic flow.

The complete traffic model under manual operation is described by equations (1), (2), (3), (4) with $w_i(n)$ defined in equation (5).

The dynamics of an automated highway system are still described by (1), (2), (3), but the adopted safety policy that defines the equilibrium speed-density relationship (10) replaces (4). Furthermore, the designed control law $u(n)$ replaces the last term in (3). The complete behaviour is governed by these equations repeated below for convenience.

\begin{align*}
q_i(n) &= \alpha k_i(n)v_i(n) + (1 - \alpha)k_{i+1}(n)v_{i+1}(n) \\
 k_i(n+1) &= k_i(n) + \frac{T}{L_i} [q_i(n) - q_{i-1}(n) - r_i(n) - s_i(n)] \\
v_i(n+1) &= v_i(n) + \frac{T}{\tau} \{V_\alpha[k_i(n)] - v_i(n)\} \\
&\quad + \frac{T}{L_i} \frac{k_{i-1}(n)}{k_i(n) + \kappa' v_{i-1}(n)} [\sqrt{v_{i-1}(n)v_i(n)} - v_i(n)] - u_i(n) \\
V_\alpha(k_i) &= \varphi^{-1}\left(\frac{1}{k_i}\right)
\end{align*}

Here $\alpha, \kappa', \tau$ are positive constants with $0 \leq \alpha \leq 1$ and $\varphi^{-1}(\cdot)$ is the inverse function of the adopted safety policy $\varphi(\cdot)$.

### 3 Problem Statement

Traffic congestion in urban freeways is caused by adhoc velocities and headways that humans choose when they operate their vehicles. Therefore, any strategy that hopes to reduce congestion needs to remove this human subjective element and replace it with a method that directly controls the density and speed of vehicles by prescribing speed commands to individual vehicles.

Assume that the roadway has the capability of measuring mean speeds and traffic densities at each section of a lane. The goal of traffic management then is to assess the state of the traffic and provide appropriate speed commands to the vehicles at various sections of the lane in order to maintain a desired traffic density profile which under the current traffic conditions corresponds to some optimum traffic flow situation. A roadway controller can be designed to perform this task. The speed commands should be generated so that the desired traffic flow rate can be achieved and the density distribution along the lane leads to a homogeneous traffic flow.
Consider a lane which is subdivided into $N$ sections with lengths $L_i, (i = 1, \ldots, N)$ as shown in Figure 1.

The traffic flow rate entering section 1 at sampling time $nT$ is $q_0(n) \text{veh/hr}$. The desired traffic density for section $i$ of a single lane is assumed to be $k_{d_i}(n)$.

Our objective is to choose a proper value of $u_i(n)$ for section $i$ such that the traffic density of section $i$ converges to the desired traffic density $k_{d_i}(n)$ exponentially fast, i.e.

$$k_i(n) \to k_{d_i}(n) \text{ as } n \to \infty.$$ 

4 Roadway Traffic Density Controller

In this section, we propose a macroscopic roadway traffic density controller for a single lane of a freeway with no on-ramp/ off-ramp traffic so that $r_i(n) = s_i(n) = 0$. Our design uses integrator backstepping to realize the control law needed to track a desired density profile. We shall repeatedly use the following lemma for this purpose.

**Lemma 4.1** Consider the following discrete time system

$$z(n+1) = cz(n) + u(n), \quad z(0) = z_0$$

where $c$ is a constant and $|c| < 1$.

Then $u(n) \to 0$ exponentially implies $z(n) \to 0$ exponentially.

**Proof:** The proof is trivial and is omitted.

Q.E.D.

Our control design consists of three steps.

**Step 1**

We begin our design by defining the tracking error for section $i$ as

$$\xi_i(n) := k_i(n) - k_{d_i}(n)$$

Then with (2) it follows that

$$\xi_i(n+1) = k_i(n+1) - k_{d_i}(n+1)$$

$$= k_i(n) + \frac{T}{k_i} [q_{i-1}(n) - q_i(n)] - k_{d_i}(n+1)$$

$$= c \xi_i(n) + \eta_i(n)$$

(15) \hspace{1cm} (16)
where
\[ \eta_i(n) := \frac{T}{L_i} [q_{i-1}(n) - q_i(n)] - k_{d_i}(n + 1) + k_i(n) - c_i \xi_i(n) \]

From Lemma 4.1, we have \( \xi_i(n) \to 0 \) as \( n \to \infty \) if \( |c_i| < 1 \) and \( q_i(n) \to 0 \) as \( n \to \infty \).

The goal of our next step is to choose the control input \( u_i(n) \) that guarantees \( \eta_i(n) \to 0 \) as \( n \to \infty \).

**Step 2**

From the definition of \( \eta_i(n) \) and (1), we have
\[ \eta_i(n) = \frac{T}{L_i} \left[ ak_{i-1}(n)v_{i-1}(n) + (1 - 2\alpha)k_i(n)v_i(n) \right] - (1 - \alpha)k_{i+1}(n)v_{i+1}(n)] - k_{d_i}(n + 1) + k_i(n) - c_i \xi_i(n) \]  
(17)

To simplify the notation, we define
\[ a_i(n) := \frac{T}{L_i} ak_{i-1}(n) \]  
(18)
\[ b_i(n) := \frac{T}{L_i} (1 - 2\alpha)k_i(n) \]  
(19)
\[ c_i(n) := -\frac{T}{L_i} (1 - \alpha)k_{i+1}(n) \]  
(20)
\[ d_i(n) := k_i(n) - c_i(n) - k_{d_i}(n + 1) \]  
(21)

Note from (2) and (15) that
\[ k_{i-1}(n + 1) = k_{i-1}(n) + \frac{T}{L_{i-1}} [q_{i-2}(n) - q_{i-1}(n)] \]
\[ k_i(n + 1) = k_i(n) + \frac{T}{L_i} [q_{i-1}(n) - q_i(n)] \]
\[ k_{i+1}(n + 1) = k_{i+1}(n) + \frac{T}{L_{i+1}} [q_i(n) - q_{i+1}(n)] \]
\[ \xi_i(n + 1) = k(n) + \frac{T}{L_i} [q_{i-1}(n) - q_i(n)] - k_{d_i}(n + 1) \]

Therefore, the quantities \( a_i(n + 1), b_i(n + 1), c_i(n + 1), d_i(n + 1) \) are available at sampling time \( nT \). To stress this fact, we define
\[ \begin{align*}
\bar{a}_i(n) &:= a_i(n + 1) \\
\bar{b}_i(n) &:= b_i(n + 1) \\
\bar{E}_i(n) &:= c_i(n + 1) \\
\bar{d}_i(n) &:= d_i(n + 1)
\end{align*} \]
(22)
Substituting our definitions (18)-(21) in equation (17) we obtain the compact form

\[ \eta_i(n) = a_i(n)v_{i-1}(n) + b_i(n)v_i(n) + c_i(n)v_{i+1}(n) + d_i(n) \]  

(23)

Then with (22) it follows that

\[ \eta_i(n + 1) = a_i(n + 1)v_{i-1}(n + 1) + b_i(n + 1)v_i(n + 1) + c_i(n + 1)v_{i+1}(n + 1) + d_i(n + 1) \]

\[ = \bar{a}_i(n)v_{i-1}(n + 1) + \bar{b}_i(n)v_i(n + 1) + \bar{c}_i(n)v_{i+1}(n + 1) + \bar{d}_i(n) \]  

(24)

We now consider the dynamics of this equation for the entrance \((i = 1)\), exit \((i = N)\) and for the intermediate sections \((1 < i < N)\) of the freeway lane. Let us first define

\[ f_i(n) := v_i(n) + \frac{T}{\tau} \{ \nu_i(k_i(n)) - v_i(n) \} \]

\[ + \frac{T}{L_i \cdot k_i(n) + \kappa^i} v_{i-1}(n) \left[ \sqrt{v_{i-1}(n)v_i(n)} - v_i(n) \right] \]  

(25)

Then, using equations (13) and (25), we have

\[ v_i(n + 1) = f_i(n) - u_i(n) \]  

(26)

**Case i: 1 < i < N for intermediate freeway sections.**

Using equations (24) and (26), we have

\[ \eta_i(n + 1) = \bar{a}_i(n)[f_{i-1}(n) - u_{i-1}(n)] + \bar{b}_i(n)[f_i(n) - u_i(n)] \]

\[ + \bar{c}_i(n)[f_{i+1}(n) - u_{i+1}(n)] + \bar{d}_i(n) \]

\[ = [\bar{a}_i(n)f_{i-1}(n) + \bar{b}_i(n)f_i(n) + \bar{c}_i(n)f_{i+1}(n) + \bar{d}_i(n)] \]

\[ - [\bar{a}_i(n)u_{i-1}(n) + \bar{b}_i(n)u_i(n) + \bar{c}_i(n)u_{i+1}(n)] \]

\[ = c_{\eta} \eta_i(n) + e_i(n) = [\bar{a}_i(n)u_{i-1}(n) + \bar{b}_i(n)u_i(n) + \bar{c}_i(n)u_{i+1}(n)] \]  

(27)

where

\[ e_i(n) := -c_{\eta} \eta_i(n) + [\bar{a}_i(n)f_{i-1}(n) + \bar{b}_i(n)f_i(n) + \bar{c}_i(n)f_{i+1}(n) + \bar{d}_i(n)] \]  

(28)

Therefore, if we choose the control signal \(u_i(n)\), \(1 < i < N\) to satisfy

\[ \bar{a}_i(n)u_{i-1}(n) + \bar{b}_i(n)u_i(n) + \bar{c}_i(n)u_{i+1}(n) = e_i(n) \]  

(29)

and choose \(c_{\eta}\) so that \(|c_{\eta}| < 1\), then by application of lemma 4.1 to equation (27) we have \(\eta_i(n) \to 0\) as \(n \to \infty\).
Case ii: \( i = 1 \) for freeway entrance.

Using boundary condition (7) in equation (24) we have

\[
\eta_1(n + 1) = (\bar{a}_1(n) + \bar{b}_1(n))v_1(n + 1) + \bar{c}_1(n)v_2(n + 1) + \bar{d}_1(n)
\]  

(30)

Substituting for \( \bar{\sigma}(n) \) and \( \bar{b}_1(n) \) from (22) and (18)-(19) in this equation and using boundary condition (6) we have

\[
\eta_1(n + 1) = \frac{T}{L_1} (\alpha k_0(n + 1) + (1 - 2\alpha)k_1(n + 1)) v_1(n + 1) + \bar{c}_1(n)v_2(n + 1) + \bar{d}_1(n)
\]

\[
= \frac{T}{L_1} (q_0(n + 1) - \alpha k_1(n + 1)v_1(n + 1)) + \bar{c}_1(n)v_2(n + 1) + \bar{d}_1(n) + \frac{T}{L_1} q_0(n + 1)
\]

\[
= \frac{\alpha}{2\alpha - 1} \bar{b}_1(n)v_1(n + 1) + \bar{c}_1(n)v_2(n + 1) + \bar{d}_1(n) + \frac{T}{L_1} q_0(n + 1)
\]

\[
= \left[ \frac{\alpha}{2\alpha - 1} \bar{b}_1(n)f_1(n) + \bar{c}_1(n)f_2(n) + \bar{d}_1(n) + \frac{T}{L_1} q_0(n + 1) \right]
\]

\[
- \left[ \frac{\alpha}{2\alpha - 1} \bar{b}_1(n)u_1(n) + \bar{c}_1(n)u_2(n) \right]
\]

\[
= c_\eta \eta_1(n) + e_1(n) - \left[ \frac{\alpha}{2\alpha - 1} \bar{b}_1(n)u_1(n) + \bar{c}_1(n)u_2(n) \right]
\]

(31)

where

\[
e_1(n) := -c_\eta \eta_1(n) + \left[ \frac{\alpha}{2\alpha - 1} \bar{b}_1(n)f_1(n) + \bar{c}_1(n)f_2(n) + \bar{d}_1(n) + \frac{T}{L_1} q_0(n + 1) \right].
\]

(32)

Therefore, if we choose control \( u_1(n) \) to satisfy

\[
\frac{\alpha}{2\alpha - 1} \bar{b}_1(n)u_1(n) + \bar{c}_1(n)u_2(n) = e_1(n)
\]

(33)

then by application of lemma 4.1 to equation (31) we have \( \eta_1(n) \to 0 \) as \( n \to \infty \).

Case iii: \( i = N \) for freeway exit.

Using boundary condition (9) in (24) we have

\[
\eta_N(n + 1) = \bar{a}_N(n)v_{N-1}(n + 1) + (\bar{b}_N(n) + \bar{c}_N(n))v_N(n + 1) + \bar{d}_N(n).
\]

(34)

Substituting for \( \bar{b}_N(n) \) and \( \bar{c}_N(n) \) from (22) and (19)-(20) in this equation and using boundary condition (8) we have

\[
\eta_N(n + 1) = \bar{a}_N(n)v_{N-1}(n + 1) + \frac{T}{L_N} ((1 - 2\alpha)k_N(n + 1) - (1 - \alpha)k_N(n + 1)) v_N(n + 1)
\]

\[
+ \bar{d}_N(n)
\]
\[ = \bar{a}_N(n)v_{N-1}(n + 1) + \frac{\alpha}{2\alpha - 1} \bar{b}_N(n)v_N(n + 1) + \bar{d}_N(n) \]

\[ = \left[ \bar{a}_N(n)f_{N-1}(n) + \frac{\alpha}{2\alpha - 1} \bar{b}_N(n)f_N(n) + \bar{d}_N(n) \right] \]

\[ - \left[ \bar{a}_N(n)u_{N-1}(n) + \frac{\alpha}{2\alpha - 1} \bar{b}_N(n)u_N(n) \right] \]

\[ = c_n\eta_N(n) + e_N(n) - \left[ \bar{a}_N(n)u_{N-1}(n) + \frac{\alpha}{2\alpha - 1} \bar{b}_N(n)u_N(n) \right] \] (35)

where

\[ e_N(n) := -c_n\eta_N(n) + \left[ \bar{a}_N(n)f_{N-1}(n) + \frac{\alpha}{2\alpha - 1} \bar{b}_N(n)f_N(n) + \bar{d}_N(n) \right]. \] (36)

Therefore, if we choose control \( u_N(n) \) to satisfy

\[ \bar{a}_N(n)u_{N-1}(n) + \frac{\alpha}{2\alpha - 1} \bar{b}_N(n)u_N(n) = e_N(n) \] (37)

then by application of lemma 4.1 to equation (35) we have \( \eta_N(n) \rightarrow 0 \) as \( n \rightarrow \infty \).

**Step 3**

To obtain the control law \( u_i(n), i=1,2,\ldots, N \) from equations (29),(33), and (37), we need to solve the algebraic equation,

\[ P_1(n)U(n) = E(n) \] (38)

where

\[
P_1(n) := \begin{bmatrix}
\frac{\alpha}{2\alpha - 1} \bar{b}_1(n) & \bar{c}_1(n) & 0 & \cdots & 0 \\
\bar{a}_2(n) & \bar{b}_2(n) & \bar{c}_3(n) & 0 & \cdots & 0 \\
0 & \bar{a}_3(n) & \bar{b}_3(n) & \bar{c}_3(n) & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 & \bar{c}_{N-1}(n) & \cdots & 0 \\
0 & 0 & \cdots & 0 & 0 & \bar{a}_N(n) & \frac{\alpha}{2\alpha - 1} \bar{b}_N(n)
\end{bmatrix}
\]

\[
U(n) := \begin{bmatrix}
u_1(n) \\
u_2(n) \\
u_3(n) \\
\vdots \\
u_N(n)
\end{bmatrix}, \quad E(n) := \begin{bmatrix}e_1(n) \\
e_2(n) \\
e_3(n) \\
\vdots \\
e_N(n)
\end{bmatrix}
\]
and
\[
e_1(n) = -c_n\eta(n) + \frac{\alpha}{2\alpha - 1} \tilde{b}_1(n)f_1(n) + \tilde{c}_1(n)f_2(n) + \tilde{d}_1(n) + \frac{T}{L_1} q_0(n + 1)
\]
\[
e_i(n) = -c_n\eta(n) + a_i(n)f_{i-1}(n) + \tilde{b}_i(n)f_i(n) + \tilde{c}_i(n)f_{i+1}(n) + \tilde{d}_i(n) \quad V_i = 2, 3, \ldots, N - 1
\]
\[
e_N(n) = -c_n\eta_N(n) + a_N(n)f_{N-1}(n) + \frac{\alpha}{2\alpha - 1} \tilde{b}_N(n)f_N(n) + \tilde{d}_N(n)
\]

We define two constants \( \rho_i, \beta_i \) where
\[
\rho_i = \frac{L_i}{L_{i+1}} \frac{\alpha}{1 - 2\alpha} < 0 \\
\beta_i = \frac{-L_i}{L_{i-1}} \frac{1 - \alpha}{1 - 2\alpha} > 0
\]

Substituting equations (39)-(40) to the tridiagonal matrix equation (38) yields
\[
P(n) U(n) = E(n)
\]

where
\[
P(n) := \begin{bmatrix}
\frac{\alpha}{2\alpha - 1} b_1(n) & \beta_1 \tilde{b}_2(n) & 0 & \cdots & 0 \\
\rho_2 b_1(n) & \sigma_2(n) & \beta_2 \tilde{b}_3(n) & 0 & \cdots & 0 \\
0 & \rho_3 \tilde{b}_2(n) & \tilde{b}_3(n) & \beta_3 \tilde{b}_3(n) & 0 & \cdots & 0 \\
0 & 0 & \cdots & \cdots & 0 & 0 \\
0 & 0 & \cdots & \cdots & 0 & \cdots & \cdots & \cdots & \beta_{N-1} \tilde{b}_N(n) \\
0 & 0 & \cdots & \cdots & 0 & \cdots & \cdots & \cdots & \cdots & \tilde{b}_N(n)
\end{bmatrix}
\]

The uniqueness of the solution of (41) depends on the non-singularity of \( P(n) \), which in turn can be guaranteed if
\[
b_i(n) \geq \delta > 0, \text{ for all } i, n.
\]

To ensure satisfaction of this condition we make the following assumption. For each section of a freeway lane at any sampling time.

**Assumption 4.1 Traffic Flow Controllability**

There exists a small positive constant \( \delta^* \) such that
\[
k_i(n + 1) = k_i(n) + \frac{T}{L_i} [\alpha k_{i-1}(n)v_{i-1}(n) + (1 - 2\alpha)k_i(n)v_i(n) - (1 - \alpha)k_{i+1}(n)v_{i+1}(n)] \\
\geq \delta^* > 0 \quad V_i, n.
\]
Remark If assumption (4.1) is violated, it implies quantitatively that the solution to equation (41) is not unique. It also implies qualitatively that the density at the next sampling instant is not sufficient to warrant control action. Hence if this condition occurs, then the control law for this section can be switched off. The requirement in assumption (4.1) is therefore intuitively reasonable for applying control.

Our design is summarized in the following theorem.

**Theorem 4.2** Assume that the traffic flow controllability stated in Assumption 4.1 is satisfied for each section at any sampling time. Let \( a \) be a positive constant defined as in table 1. Let,

\[
\begin{align*}
\rho_i &:= \frac{L_i \alpha}{L_{i+1} (1 - 2\alpha)} < 0 \text{ for } i = 2, 3, \ldots, N \\
\beta_i &:= \frac{1 - a}{L_i (1 - 2\alpha)} > 0 \text{ for } i = 1, 2, \ldots, N - 1 \\
\bar{b}_i(n) &= \frac{T}{L_i} (1 - 2\alpha) k_i(n + 1) \text{ for } i = 1, 2, \ldots, N
\end{align*}
\]

\[
\begin{bmatrix}
\frac{\alpha L_i}{2\alpha - 1} b_1(n) & \beta_1 b_2(n) & 0 & \cdots & 0 \\
\rho_2 b_1(n) & b_2(n) & \beta_2 b_3(n) & 0 & \cdots & 0 \\
0 & \rho_3 b_2(n) & b_3(n) & \cdots & \cdots & 0 \\
0 & 0 & 0 & \cdots & \cdots & 0 \\
0 & 0 & 0 & \cdots & \cdots & \beta_{N-1} b_N(n) \\
0 & 0 & 0 & \cdots & \cdots & \rho_N b_{N-1}(n) \frac{\alpha}{2\alpha - 1} b_N(n)
\end{bmatrix}
\]

\[
\begin{bmatrix}
u_1(n) \\ u_2(n) \\ u_3(n) \\ \vdots \\ u_N(n)
\end{bmatrix}
= \begin{bmatrix}
e_1(n) \\ e_2(n) \\ e_3(n) \\ \vdots \\ e_N(n)
\end{bmatrix}
\]

where \( e_i(n) \) for \( i = 2, 3, \ldots, N - 1 \) and \( e_N(n) \) are as defined in (32), (28) and (36) respectively. Then there exists a control input \( v_i(n) \) which satisfies

\[
P(n) U(n) = E(n)
\]

and furthermore, drives the traffic density \( k_i(n) \) for section \( i, i = 1, 2, \ldots, N \) to the desired traffic density \( k_{di}(n) \) exponentially fast.
Proof: We found in Step 3 that the desired control law must satisfy the matrix equation (42). This provides the solution for the algebraic equations (29), (33) and (37) in Step 2. Application of Lemma 4.1 along with this solution to equations (27), (31) and (35) yields \( \eta_i(n) \to 0 \) as \( n \to \infty, \forall i \). Use of the same Lemma to equation (16) ensures that \( \xi_i(n) \to 0 \) as \( n \to \infty, \forall i \). Hence \( \eta_i(n) \to k_{d_i}(n) \) exponentially. Q.E.D.

Theorem 4.2 provides the control strategy needed for tracking of a desired density profile. According to this theorem, if the velocity command that is sent to vehicles in each section \( i \) of the lane at sampling time \( (n + 1)T \) is chosen as

\[
v_{\text{command}} = v_i(n) + \frac{T}{\tau} \{ V_c[k_i(n)] - w_i(n) \} + \frac{T}{k_i(n)} \left( k_{i-1}(n) - \sqrt{v_{i-1}(n)v_i(n)} \right) - u_i(n)
\]

where \( u_i(n) \) is chosen as (42), then the traffic density at section \( i \) converges to the desired traffic density \( k_{d_i} \) exponentially.

5 Simulation Studies

Consider a long segment of freeway with only one lane which is divided into 12 sections. The length of each section is 500m. The initial traffic volume entering section 1 is assumed to be 1500 veh/h. Initial density and mean speed of each section are as shown in table 2.

Table 2: Initial densities and velocities of a single lane freeway

Four cases are considered. In the first case, we show in figures 2 and 3 the situation when no control is applied. From these figures we see the propagation of congestion upstream due to the initial traffic congestion in sections 6 \(-\) 8 which eventually causes a traffic jam.

In the second and third cases, we use our proposed controller to achieve desired traffic densities of 23 and 35 veh/km respectively. As evidenced by our simulation results shown

13
in figures 4-9, the initial congested conditions are quickly dampened out by our controller and traffic flow is regulated to achieve the desired traffic densities.

In the fourth case, we assume that the input traffic flow rate in section 1 increases exponentially from 1500 $veh/h$ to 2000 $veh/h$ as shown in figure 10. We set the desired traffic density for this case to 23 $veh/km$. From our simulation results shown in figure 11 we see that the desired traffic density is exponentially achieved.

6 Conclusion

In this paper, we presented the theory and design of a macroscopic traffic controller to track a desired density profile. Our simulations demonstrated the effectiveness of our controller in reducing traffic congestion and exponentially tracking desired densities. However, due to the highly nonlinear and strong coupling characteristics of the freeway model, computation of the control required for density tracking is not straightforward. First, it needs density and velocity data of all sections of the freeway. The cost of data acquisition for this purpose increases with the freeway length and can be substantial. Second, computation of the control involves a recursive type algebraic equation formed by (29), (33) and (37) which leads to a large scale matrix equation (41) that must be solved. The solution of this equation yields the control that must be applied for all sections of the freeway under consideration. Computational costs associated with solving such large scale systems can be considerable and should be avoided for quick and effective control. Due to these concerns, it is desirable to move from a centralized controller to a decentralized one. Such a controller should apply control on a particular section based only on the information from its neighboring sections. Furthermore, any computations necessary in determining this control should not be unnecessarily costly. The design of decentralized controllers that achieve these objectives is a topic of current research.
